# Low-Jitter, 10-Port LVDS Repeater

### **General Description**

The MAX9150 low-jitter, 10-port, low-voltage differential signaling (LVDS) repeater is designed for applications that require high-speed data or clock distribution while minimizing power, space, and noise. The device accepts a single LVDS input and repeats the signal at 10 LVDS outputs. Each differential output drives a total of 50 $\Omega$ , allowing point-to-point distribution of signals on transmission lines with  $100\Omega$  terminations on each end.

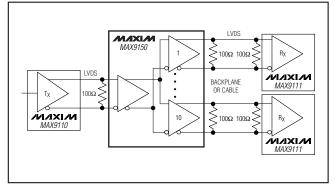

Ultra-low 120ps (max) peak-to-peak jitter (deterministic and random) ensures reliable communication in highspeed links that are highly sensitive to timing error, especially those incorporating clock-and-data recovery, or serializers and deserializers. The high-speed switching performance guarantees 400Mbps data rate and less than 100ps skew between channels while operating from a single +3.3V supply.

Supply current at 400Mbps is 160mA (max) and is reduced to 60µA (max) in low-power shutdown mode. Inputs and outputs conform to the EIA/TIA-644 LVDS standard. A fail-safe feature sets the outputs high when the input is undriven and open, terminated, or shorted. The MAX9150 is available in a 28-pin TSSOP package.

Refer to the MAX9110/MAX9112 and MAX9111/MAX9113 data sheets for LVDS line drivers and receivers.

**Applications** Cellular Phone Base Stations Add/Drop Muxes **Digital Crossconnects** Network Switches/Routers Backplane Interconnect **Clock Distribution** 

## **Typical Application Circuit**

## 

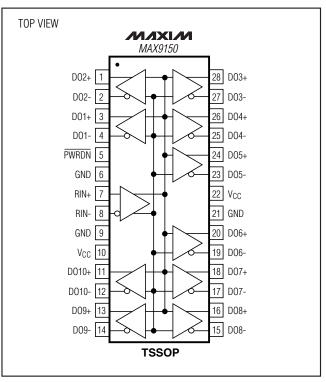

**Features** 

- Ultra-Low 120psp-p (max) Total Jitter (Deterministic and Random)
- 100ps (max) Skew Between Channels
- Guaranteed 400Mbps Data Rate
- 60µA Shutdown Supply Current
- Conforms to EIA/TIA-644 LVDS Standard
- Single +3.3V Supply
- ♦ Fail-Safe Circuit Sets Output High for Undriven Inputs
- High-Impedance LVDS Input when VCC = 0V

## **Ordering Information**

PART	TEMP. RANGE	PIN-PACKAGE
MAX9150EUI	-40°C to +85°C	28 TSSOP

## Pin Configuration

**MAX9150** 

#### **Pin Description**

PIN	NAME	FUNCTION
1, 3, 11, 13, 16, 18, 20, 24, 26, 28	DO2+, DO1+, DO10+, DO9+, DO8+, DO7+, DO6+, DO5+, DO4+, DO3+	Differential LVDS Outputs. Connect a $100\Omega$ resistor across each of the output
2, 4, 12, 14, 15, 17, 19, 23, 25, 27	DO2-, DO1-, DO10-, DO9-, DO8-, DO7-, DO6-, DO5-, DO4-, DO3-	pairs (DO_+ and DO) adjacent to the IC, and connect a 100 $\Omega$ resistor at the input of the receiving circuit.
5	PWRDN	Power Down. Drive $\overline{\text{PWRDN}}$ low to disable all outputs and reduce supply current to 60 $\mu$ A. Drive $\overline{\text{PWRDN}}$ high for normal operation.
6, 9, 21	GND	Ground
10, 22	V <sub>CC</sub>	Power. Bypass each $V_{CC}$ pin to GND with 0.1 $\mu F$ and 1nF ceramic capacitors.
7	RIN+	LVDS Receiver Inputs. RIN+ and RIN- are high-impedance inputs. Connect a
8	RIN-	resistor from RIN+ to RIN- to terminate the input signal.

#### **Detailed Description**

The LVDS interface standard is a signaling method intended for point-to-point communication over a controlled impedance medium, as defined by the ANSI/TIA/EIA-644 and IEEE 1596.3 standards. The LVDS standard uses a lower voltage swing than other common communication standards, achieving higher data rates with reduced power consumption while reducing EMI emissions and system susceptibility to noise.

The MAX9150 is a 400Mbps, 10-port LVDS repeater intended for high-speed, point-to-point, low-power applications. This device accepts an LVDS input and repeats it on 10 LVDS outputs. The device is capable of detecting differential signals as low as 100mV and as high as 1V within a 0 to 2.4V input voltage range. The LVDS standard specifies an input voltage range of 0 to 2.4V referenced to ground.

The MAX9150 outputs use a current-steering configuration to generate a 5mA to 9mA output current. This current-steering approach induces less ground bounce and no shoot-through current, enhancing noise margin and system speed performance. The driver outputs are short-circuit current limited, and are high impedance (to ground) when  $\overline{PWRDN}$  = low or the device is not powered. The outputs have a typical differential resistance of 240 $\Omega$ .

The MAX9150 current-steering architecture requires a resistive load to terminate the signal and complete the

transmission loop. Because the device switches the direction of current flow and not voltage levels, the output voltage swing is determined by the total value of the termination resistors multiplied by the output current. With a typical 6.4mA output current, the MAX9150 produces a 320mV output voltage when driving a transmission line terminated at each end with a 100 $\Omega$  termination resistor (6.4mA x 50 $\Omega$  = 320mV). Logic states are determined by the direction of current flow through the termination resistors.

#### Fail-Safe

Fail-safe is a receiver feature that puts the output in a known logic state (high) under certain fault conditions. The MAX9150 outputs are differential high when the inputs are undriven and open, terminated, or shorted (Table 1).

Table 1. Input/Output Function Tab
------------------------------------

INPU	T, V <sub>ID</sub>	OUTPUTS, V <sub>OD</sub>		
+100mV		High		
-100mV		Low		
Open		High		
Short	Undriven	High		
Terminated	Undriven	High		

**Note:**  $V_{ID} = RIN+ - RIN-, V_{OD} = DO_+ - DO_-$ High = 450mV >  $V_{OD} > 250mV$ Low = -250mV >  $V_{OD} > -450mV$ 

#### **Applications Information**

#### **Supply Bypassing**

Bypass each of the V<sub>CC</sub> pins with high-frequency surface-mount ceramic 0.1 $\mu$ F and 1nF capacitors in parallel as close to the device as possible, with the smaller valued capacitor closest to the V<sub>CC</sub> pins.

#### **Differential Traces**

Output trace characteristics affect the performance of the MAX9150. Use controlled impedance traces to match trace impedance to both the transmission medium impedance and termination resistor. Ensure that noise couples as common mode by running the differential traces close together. Reduce skew by matching the electrical length of the traces. Excessive skew can result in a degradation of magnetic field cancellation.

Maintain the distance between the differential traces to avoid discontinuities in differential impedance. Avoid 90° turns and minimize the number of vias to further prevent impedance discontinuities.

#### **Cables and Connectors**

Transmission media should have a controlled differential impedance of  $100\Omega$ . Use cables and connectors that have matched differential impedance to minimize impedance discontinuities.

Avoid the use of unbalanced cables, such as ribbon or simple coaxial cable. Balanced cables, such as twisted pair, offer superior signal quality and tend to generate less EMI due to canceling effects. Balanced cables tend to pick up noise as common mode, which is rejected by the LVDS receiver.

#### Termination

**MAX9150** 

Termination resistors should match the differential characteristic impedance of the transmission line. Since the MAX9150 has current-steering devices, an output voltage will not be generated without a termination resistor. Output voltage levels are dependent upon the value of the total termination resistance. The MAX9150 produces LVDS output levels for point-to-point links that are double terminated (100 $\Omega$  at each end). With the typical 6.4mA output current, the MAX9150 produces an output voltage of 320mV when driving a transmission line terminated at each end with a 100 $\Omega$  termination resistor (6.4mA x 50 $\Omega$  = 320mV). Termination resistance values may range between 90 $\Omega$  and 150 $\Omega$ , depending on the characteristic impedance of the transmission medium.

Minimize the distance between the output termination resistor and the corresponding MAX9150 transmitter output. Use  $\pm 1\%$  surface-mount resistors.

Minimize the distance between the input termination resistor and the MAX9150 receiver input. Use a  $\pm 1\%$  surface-mount resistor.
