www.onsemi.com

Please note: As part of the Fairchild Semiconductor integration, some of the Fairchild orderable part numbers will need to change in order to meet ON Semiconductor's system requirements. Since the ON Semiconductor product management systems do not have the ability to manage part nomenclature that utilizes an underscore (_), the underscore (_) in the Fairchild part numbers will be changed to a dash (-). This document may contain device numbers with an underscore (_). Please check the ON Semiconductor website to verify the updated device numbers. The most current and up-to-date ordering information can be found at www.onsemi.com. Please email any questions regarding the system integration to Fairchild_questions@onsemi.com.

FAN48630 — 2.5 MHz, 1500 mA, Synchronous TinyBoost® Regulator with Bypass Mode

Features

- Few External Components: 0.47 µH Inductor and 0603 Case Size Input and Output Capacitors
- Input Voltage Range: 2.35 V to 5.5 V
- Fixed Output Voltage Options: 3.0 V to 5.0 V
- Maximum Continuous Load Current: 1500 mA at V_{IN} of 2.6 V Boosting V_{OUT} to 3.5 V
- Up to 96% Efficient
- True Bypass Operation when $V_{IN} > V_{OUT\_TARGET}$
- Internal Synchronous Rectifier
- Soft-Start with True Load Disconnect
- Forced Bypass Mode
- V_{SEL} Control to Optimize Target V_{OUT}
- Short-Circuit Protection
- Low Operating Quiescent Current
- 16-Bump, 0.4 mm Pitch WLCSP

Applications

- Boost for Low-Voltage Li-ion Batteries, Brownout Prevention, Boosted Audio, USB OTG, and LTE / 3G RF Power
- Cell Phones, Smart Phones, Portable Instruments

Description

The FAN48630 allows systems to take advantage of new battery chemistries that can supply significant energy when the battery voltage is lower than the required voltage for system power ICs. By combining built-in power transistors, synchronous rectification, and low supply current; this IC provides a compact solution for systems using advanced Li-Ion battery chemistries.

The FAN48630 is a boost regulator designed to provide a minimum output voltage from a single-cell Li-Ion battery, even when the battery voltage is below system minimum. Output voltage regulation is guaranteed to a maximum load current of 1500 mA. Quiescent current in Shutdown Mode is less than 3 µA, which maximizes battery life. The regulator transitions smoothly between Bypass and normal Boost Mode. The device can be forced into Bypass Mode to reduce quiescent current.

The FAN48630 is available in a 16-bump, 0.4 mm pitch, Wafer-Level Chip-Scale Package (WLCSP).

Pin Configuration

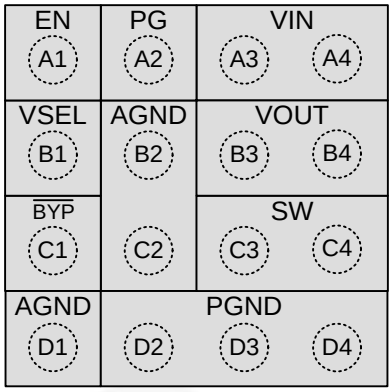

Figure 3. Top Through View (Bumps Down)

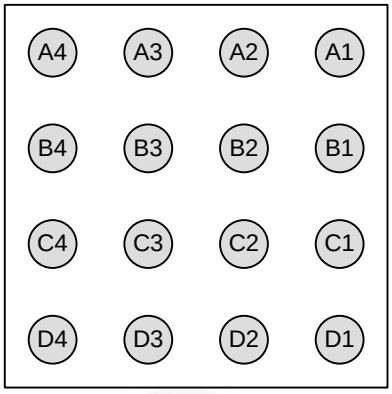

Figure 4. Bottom View (Bumps Up)

Pin Definitions

Pin #	Name	Description
A1	EN	**Enable**. When this pin is HIGH, the circuit is enabled.[3]
A2	PG	**Power Good**. This is an open-drain output. PG is actively pulled LOW if output falls out of regulation due to overload or if thermal protection threshold is exceeded.
A3–A4	VIN	**Input Voltage**. Connect to Li-Ion battery input power source.[3]
B1	VSEL	**Output Voltage Select**. When boost is running, this pin can be used to select output voltage.
B2, C2 D1	AGND	**Analog Ground**. This is the signal ground reference for the IC. All voltage levels are measured with respect to this pin.
B3–B4	VOUT	**Output Voltage**. Place C_{OUT} as close as possible to the device.
C1	$\overline{BYP}$	**Bypass**. This pin can be used to activate Forced Bypass Mode. When this pin is LOW, the bypass switches (Q3 and Q1) are turned on and the IC is otherwise inactive.
C3–C4	SW	**Switching Node**. Connect to inductor.
D2–D4	PGND	**Power Ground**. This is the power return for the IC. The C_{OUT} bypass capacitor should be returned with the shortest path possible to these pins.

Note:

3. Do not connect the EN pin to VIN. A logic voltage of 1.8 V should control the EN pin and enable / disable the device.

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Symbol	Parameter		Min.	Max.	Unit
V_{IN}	V_{IN} Input Voltage		-0.3	6.5	V
V_{OUT}	V_{OUT} Output Voltage			6.0	V
	SW Node	DC	-0.3	8.0	V
		Transient: 10 ns, 3 MHz	-1.0	8.0	V
	Other Pins		-0.3	6.5[4]	V
ESD	Electrostatic Discharge Protection Level	Human Body Model per JESD22-A114	3.0		kV
		Charged Device Model per JESD22-C101	1.5		kV
T_J	Junction Temperature		-40	+150	°C
T_{STG}	Storage Temperature		-65	+150	°C
T_L	Lead Soldering Temperature, 10 Seconds			+260	°C

Note:

4. Lesser of 6.5 V or V_{IN} + 0.3 V.

Recommended Operating Conditions

The Recommended Operating Conditions table defines the conditions for actual device operation. Recommended operating conditions are specified to ensure optimal performance to the datasheet specifications. Fairchild does not recommend exceeding them or designing to absolute maximum ratings.

Symbol	Parameter	Min.	Max.	Unit
V_{IN}	Supply Voltage	2.35	5.50	V
I_{OUT}	Output Current	0	1500	mA
T_A	Ambient Temperature	-40	+85	°C
T_J	Junction Temperature	-40	+125	°C

Thermal Properties

Junction-to-ambient thermal resistance is a function of application and board layout. This data is measured with four-layer Fairchild evaluation boards (1 oz copper on all layers). Special attention must be paid not to exceed junction temperature $T_{J(max)}$ at a given ambient temperate T_A.

Symbol	Parameter	Typical	Unit
θ_{JA}	Junction-to-Ambient Thermal Resistance	80	°C/W
θ_{JB}	Junction-to-Board Thermal Resistance	42	

Electrical Specifications

Recommended operating conditions, unless otherwise noted, circuit per Figure 1, V_{IN} = 2.35 V to V_{OUT}, T_A = -40˚C to 85˚C. Typical values are given V_{IN} = 3.0 V and T_A = 25˚C.

Symbol	Parameter	Conditions		Min.	Typ.	Max.	Unit

Circuit Description

FAN48630 is a synchronous boost regulator, typically operating at 2.5 MHz in Continuous Conduction Mode (CCM), which occurs at moderate to heavy load current and low V_{IN} voltages. The regulator includes a Bypass Mode that activates when V_{IN} is above the boost regulator's setpoint.

In anticipation of a heavy load transition, the setpoint can be adjusted upward by fixed amounts with the VSEL pin to reduce the required system headroom during lighter-load operation to save power.

Table 2. Operating States

Mode	Description	Invoked When
LIN	Linear Startup	$V_{IN} > V_{OUT}$
SS	Boost Soft-Start	$V_{OUT} < V_{OUT\_TARGET}$
BST	Boost Operating Mode	$V_{OUT} = V_{OUT\_TARGET}$
BPS	Bypass Mode	$V_{IN} > V_{OUT\_TARGET}$

Boost Mode

The FAN48630 uses a current-mode modulator to achieve excellent transient response and smooth transitions between CCM and Discontinuous Conduction Mode (DCM) operation. During CCM operation, the device maintains a switching frequency of about 2.5 MHz. In light-load operation (DCM), frequency is reduced to maintain high efficiency.

Table 3. Boost Startup Sequence

Start State	Entry	Exit	End State	Timeout (µs)
LIN1	V_{IN} > UVLO, EN=1	$V_{OUT} > V_{IN}$-300 mV	SS	
			LIN2	512
LIN2	LIN1 Exit	$V_{OUT} > V_{IN}$-300 mV	SS	
		TIMEOUT	FAULT	1024
SS	LIN1 or LIN2 Exit	$V_{OUT}=V_{OUT\_TARGET}$	BST	
		OVERLOAD TIMEOUT	FAULT	64

Shutdown and Startup

If EN is LOW, all bias circuits are off and the regulator is in Shutdown Mode. During shutdown, current flow is prevented from V_{IN} to V_{OUT}, as well as reverse flow from V_{OUT} to V_{IN}. During startup, it is recommended to keep DC current draw below 500 mA.

LIN State

When EN is HIGH and V_{IN} > UVLO, the regulator attempts to bring V_{OUT} within 300 mV of V_{IN} using the internal fixed current source from V_{IN} (Q3). The current is limited to LIN1 set point.

If V_{OUT} reaches V_{IN}-300 mV during LIN1 Mode, the SS state is initiated. Otherwise, LIN1 times out after 512 µs and LIN2 Mode is entered.

In LIN2 Mode, the current source is incremented to 2A. If V_{OUT} fails to reach V_{IN}-300 mV after 1024 µs, a fault condition is declared.

SS State

Upon the successful completion of the LIN state ($V_{OUT} \geq V_{IN}$-300 mV), the regulator begins switching with boost pulses current limited to 50% of nominal level.

During SS state, V_{OUT} is ramped up by stepping the internal reference. If V_{OUT} fails to reach regulation during the SS ramp sequence for more than 64 µs, a fault condition is declared. If large C_{OUT} is used, the reference is automatically stepped slower to avoid excessive input current draw.

BST State

This is a normal operating state of the regulator.

BPS State

If V_{IN} is above V_{REG} when the SS Mode successfully completes, the device transitions directly to BPS Mode.

FAST and SLOW Soft-Start Options

The fast startup versions feature EN to regulation time of 600 µs. LIN1 and LIN2 phase currents are doubled compared to SLOW options, SS phase is also faster.

Slow startup achieves EN to regulation time of 1300 µs to reduce inrush current.

Table 4. EN and $\overline{BYP}$ Logic Table

EN	$\overline{BYP}$	Mode	V_{OUT}
0	0	Shutdown	0
	1	Shutdown	0
1	0	Forced Bypass	VIN
	1	Auto Bypass	V_{OUT_TARGET} or V_{IN} (if $V_{IN} > V_{OUT\_TARGET}$)

FAULT State

The regulator enters the FAULT state under any of the following conditions:

- V_{OUT} fails to achieve the voltage required to advance from LIN state to SS state.
- V_{OUT} fails to achieve the voltage required to advance from SS state to BST state.
- Boost current limit triggers for 2 ms during the BST state.
- V_{DS} protection threshold is exceeded during BPS state.

Once a fault is triggered, the regulator stops switching and presents a high-impedance path between V_{IN} and V_{OUT}. After waiting 20 ms, a restart is attempted.

Power Good

Power good is 0 FAULT, 1 POWER GOOD, open-drain output.

The Power good pin is provided for signaling the system when the regulator has successfully completed soft-start and no faults have occurred. Power good also functions as an early warning flag for high die temperature and overload conditions.

Over-Temperature

The regulator shuts down when the die temperature exceeds 150°C. Restart occurs when the IC has cooled by approximately 20°C.

Bypass Operation

In normal operation, the device automatically transitions from Boost Mode to Bypass Mode, if V_{IN} goes above target V_{OUT}. In Bypass Mode, the device fully enhances both Q1 and Q3 to provide a very low impedance path from VIN to VOUT. Entry to the Bypass Mode is triggered by condition where V_{IN} > V_{OUT} and no switching has occurred during past 5 µs. To soften the entry to Bypass Mode, Q3 is driven as a linear current source for the first 5 µs. Bypass Mode exit is triggered when V_{OUT} reaches the target V_{OUT} voltage. During Automatic Bypass Mode, the device is short-circuit protected by voltage comparator tracking the voltage drop from V_{IN} to V_{OUT}; if the drop exceeds 200 mV, FAULT is declared.

With sufficient load to enforce CCM operation, the Bypass Mode to Boost Mode transition occurs at the target V_{OUT}. The corresponding input voltage at the transition point is:

$$V_{IN} \le V_{OUT} + I_{LOAD} \bullet (DCR_L + R_{DS(ON)P}) \parallel R_{DS(ON)BYP} \quad \text{EQ. 1}$$

The Bypass Mode entry threshold has 25 mV hysteresis imposed at VOUT to prevent cycling between modes. The transition from Boost Mode to Bypass Mode occurs at the target V_{OUT}+25 mV. The corresponding input voltage is:

$$V_{IN} \ge V_{OUT} + 25mV + I_{LOAD} \bullet (DCR_L + R_{DS(ON)P}) \quad \text{EQ. 2}$$

- PG is released HIGH when the soft-start sequence is successfully completed.
- PG is pulled LOW when PMOS current limit has triggered for 64 µs OR the die the temperature exceeds 120°C. PG is re-asserted when the device cools below to 100°C.
- Any FAULT condition causes PG to be de-asserted.

Forced Bypass

Entry to Forced Bypass Mode initiates with a current limit on Q3 and then proceeds to a true bypass state. To prevent reverse current to the battery, the device waits until output discharges below V_{IN} before entering Forced Bypass Mode.

For Low-IQ Forced Bypass versions, after the transition is complete, most of the internal circuitry is disabled to minimize quiescent current draw. Short-circuit, UVLO, output OVP and over-temperature protections are inactive in Forced Bypass Mode.

For OCP-On Forced Bypass versions, during Forced Bypass Mode, the device is short-circuit protected by a voltage comparator tracking the voltage drop from VIN to VOUT. If the drop exceeds 200 mV, a FAULT is declared. The over-temperature protection is also active.

VSEL

V_{SEL} can be asserted in anticipation of a positive load transient. Raising V_{SEL} increases V_{OUT_TARGET} by a fixed amount and V_{OUT} is stepped to the corresponding target output voltage in 20 µs. The functionality can also be utilized to mitigate undershoot during severe line transients, while minimizing V_{OUT} during more benign operating conditions to save power.

EN

Setting the EN pin voltage below 0.4 V disables the part. Placing the voltage above 1.2 V enables the part. Do not connect the EN pin to VIN. A logic voltage of 1.8 V should control the EN pin and enable / disable the device. The EN pin should be pulled HIGH after the V_{IN} voltage has reached a minimum voltage of 2.3 V.

Application Information

Output Capacitance (C_{OUT})

Stability

The effective capacitance (C_{EFF}) of small, high-value, ceramic capacitors decreases as bias voltage increases.

FAN48630 is guaranteed for stable operation with the minimum value of C_{EFF} ($C_{EFF(MIN)}$) outlined in Table 5 below.

Table 5. Minimum C_{EFF} Required for Stability

Operating Conditions		$C_{EFF(MIN)}$ (µF)
V_{OUT} (V)	I_{LOAD} (mA)	
3.15	0 to 1500	12
3.5	0 to 1500	9
4.5 and 5	0 to 1500	6

C_{EFF} varies with manufacturer, material, and case size.

Inductor Selection

Recommended nominal inductance value is 0.47 µH.

FAN48630 employs valley-current limiting; peak inductor current can reach 3.8 A for a short duration during overload conditions. Saturation effects cause the inductor current ripple to become higher under high loading as only valley of the inductor current ripple is controlled.

For FAN48630UC315X and FAN48630UC33X, a 0.33 µH inductor can be used for improved transient performance.

Startup

Input current limiting is in effect during soft-start, which limits the current available to charge C_{OUT} and any additional capacitance on the V_{OUT} line. If the output fails to achieve regulation within the limits described in the Startup section, a FAULT occurs, causing the circuit to shut down then restart after a significant time period. If the total combined output capacitance is very high, the circuit may not start on the first attempt, but eventually achieves regulation if no load is present. If a high-current load and high capacitance are both present during soft-start, the circuit may fail to achieve regulation and continually attempts soft-start, only to have the output capacitance discharged by the load when in a FAULT state.

Output Voltage Ripple

Output voltage ripple is inversely proportional to C_{OUT}. During t_{ON}, when the boost switch is on, all load current is supplied by C_{OUT}. Output ripple is calculated as:

$$V_{RIPPLE\,(P-P)} = t_{ON} \bullet \frac{I_{LOAD}}{C_{OUT}} \quad \text{EQ. 3}$$

and

$$t_{ON} = t_{SW} \bullet D = t_{SW} \bullet \left(1 - \frac{V_{IN}}{V_{OUT}}\right) \quad \text{EQ. 4}$$

therefore:

$$V_{RIPPLE\,(P-P)} = t_{SW} \bullet \left(1 - \frac{V_{IN}}{V_{OUT}}\right) \bullet \frac{I_{LOAD}}{C_{OUT}} \quad \text{EQ. 5}$$

and

$$t_{SW} = \frac{1}{f_{SW}} \quad \text{EQ. 6}$$

As can be seen from EQ. 5, the maximum V_{RIPPLE} occurs when V_{IN} is at minimum and I_{LOAD} is at maximum.

Layout Recommendations

The layout recommendations below highlight various top-copper pours using different colors.

To minimize spikes at V_{OUT}, C_{OUT} must be placed as close as possible to PGND and VOUT, as shown in Figure 29.

For thermal reasons, it is suggested to maximize the pour area for all planes other than SW. Especially the ground pour should be set to fill all available PCB surface area and tied to internal layers with a cluster of thermal vias.
