

# +2.7V to +5.5V, Low-Power, Triple, Parallel 8-Bit DAC with Rail-to-Rail Voltage Outputs

## General Description

The MAX5101 parallel-input, voltage-output, triple 8-bit digital-to-analog converter (DAC) operates from a single +2.7V to +5.5V supply and comes in a space-saving 16-pin TSSOP package. Internal precision buffers swing rail-to-rail. For all three DACs, the internal reference voltage is tied to  $V_{DD}$ .

The MAX5101 has separate input latches for each of its three DACs. Data is transferred to the input latches from a common 8-bit input port. The DACs are individually selected through address inputs A0 and A1 and are updated by bringing  $\overline{WR}$  low.

The MAX5101 features a  $1\mu\text{A}$  software shutdown mode, as well as a power-on reset mode that resets all registers to code 00 hex on power-up.

## Applications

Digital Gain and Offset Adjustment  
 Programmable Attenuators  
 Portable Instruments  
 Power-Amp Bias Control

## Features

- ◆ +2.7V to +5.5V Single-Supply Operation
- ◆ Ultra-Low Supply Current  
 0.3mA while Operating  
 1 $\mu\text{A}$  in Software Shutdown Mode
- ◆ Ultra-Small 16-Pin TSSOP Package
- ◆ Output Buffer Amplifiers Swing Rail-to-Rail
- ◆ Power-On Reset Sets All Registers to Zero

## Detailed Description

### Digital-to-Analog Section

The MAX5101 uses a matrix decoding architecture for the digital-to-analog converters (DACs). The internal reference voltage is connected to V<sub>DD</sub> and divided down by a resistor string placed in a matrix fashion. Row and column decoders select the appropriate tab from the resistor string to provide the needed analog voltages. The resistor network converts the 8-bit digital input into an equivalent analog output voltage in proportion to the supply voltage (V<sub>DD</sub>). The resistor string presents a code-independent input impedance to the supply and guarantees a monotonic output.

The voltages are buffered by rail-to-rail op amps connected in a follower configuration to provide a rail-to-rail output (see *Functional Diagram*).

### Output Buffer Amplifiers

The DAC outputs are internally buffered by a precision amplifier with a typical slew rate of 0.6V/μs. The typical settling time to ±1/2LSB at the output is 6μs when loaded with 10kΩ in parallel with 100pF.

### DAC Reference Voltage

The MAX5101's reference is internally tied to V<sub>DD</sub>. The output voltage (V<sub>OUT</sub>) for any DAC is represented by a digitally programmable voltage source as follows:

$$V_{OUT} = (N_B \cdot V_{DD}) / 256$$

where N<sub>B</sub> is the numeric value of the DAC binary input code.

### Digital Inputs and Interface Logic

In the MAX5101, address lines A0 and A1 select the DAC that receives data from D0–D7, as shown in Table 1. When  $\overline{WR}$  is low, the addressed DAC's input latch is transparent. Data is latched when  $\overline{WR}$  is high. The DAC outputs (OUTA, OUTB) represent the data held in the three 8-bit input latches. To avoid output glitches in the MAX5101, ensure that data is valid before  $\overline{WR}$  goes low.

### Low-Power Shutdown Mode

The MAX5101 features a software shutdown mode. A write performed to address A1 = H and A0 = H causes the device to shut down. A subsequent write to any of the other three addresses disables shutdown and turns the analog circuitry on. As the MAX5101 comes out of shutdown, all registers retain their digital values prior to shutdown. However, when the device powers up (i.e., V<sub>DD</sub> ramps up), all latches are internally preset with code 00 hex. In shutdown, the output amplifiers enter a high-impedance state. When bringing the device out of shutdown, allow 13μs for the output to stabilize.

### Power-Supply Bypassing and Ground Management

Digital or AC transient signals on GND can create noise at the analog output. Return GND to the highest-quality ground available. Bypass V<sub>DD</sub> with a 0.1μF capacitor, located as close to V<sub>DD</sub> and GND as possible.

Careful PC board ground layout minimizes crosstalk between the DAC outputs and digital inputs.
