

NCV890204

Buck Switching Regulator - Automotive, Programmable, Spread Spectrum, Adjustable RSTB

2.0 A, 2 MHz

The NCV890204 is a fixed-frequency, monolithic, Buck switching regulator intended for Automotive, battery-connected applications that must operate with up to a 36 V input supply. The regulator is suitable for systems with low noise and small form factor requirements often encountered in automotive driver information systems. The NCV890204 is capable of converting the typical 4.5 V to 18 V automotive input voltage range to outputs as low as 3.3 V at a constant switching frequency above the sensitive AM band, eliminating the need for costly filters and EMI countermeasures. The NCV890204 also provides several protection features expected in Automotive power supply systems such as current limit, short circuit protection, and thermal shutdown. In addition, the high switching frequency produces low output voltage ripple even when using small inductor values and an all-ceramic output filter capacitor – forming a space-efficient switching regulator solution.

Features

- Internal N-Channel Power Switch
- Low V_{IN} Operation Down to 4.5 V
- High V_{IN} Operation to 36 V
- Withstands Load Dump to 40 V
- 2 MHz Free-running Switching Frequency
- Adjustable Spread Spectrum
- Reset with Adjustable Delay
- Logic level Enable Input Can be Directly Tied to Battery
- 2.2 A (min) Cycle-by-Cycle Peak Current Limit
- Short Circuit Protection enhanced by Frequency Foldback
- $\pm 1.75\%$ Output Voltage Tolerance
- Output Voltage Adjustable Down to 0.8 V
- 1.4 Millisecond Internal Soft-Start

ORDERING INFORMATION

See detailed ordering and shipping information on page 18 of this data sheet.

- Thermal Shutdown (TSD)
- Low Shutdown Current
- Wettable Flanks DFN (pin edge plating)
- NCV Prefix for Automotive and Other Applications Requiring Unique Site and Control Change Requirements; AEC-Q100 Qualified and PPAP Capable
- These Devices are Pb-Free and are RoHS Compliant

Applications

- Audio
- Infotainment
- Safety – Vision Systems
- Instrumentation

MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Min/Max Voltage VIN, BST		-0.3 to 40	V
Max Voltage VIN to SW		40	V
Min/Max Voltage SW		-0.7 to 40	V
Min Voltage SW – 20 ns		-3.0	V
Min/Max Voltage BST to SW		-0.3 to 3.6	V
Min/Max Voltage on EN		-0.3 to 40	V
Min/Max Voltage COMP		-0.3 to 2	V
Min/Max Voltage FB		-0.3 to 18	V
Min/Max Voltage DRV, DELAY, RMOD, RDEPTH		-0.3 to 3.6	V
Min/Max Voltage RSTB		-0.3 to 6	V
Thermal Resistance, 4x4 DFN Junction-to-Ambient*	$R_{\theta JA}$	35	°C/W
Storage Temperature Range		-55 to +150	°C
Operating Junction Temperature Range	T_J	-40 to +150	°C
ESD withstand Voltage Human Body Model	V_{ESD}	2.0	kV
Moisture Sensitivity	MSL	Level 1	
Peak Reflow Soldering Temperature		260	°C

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

*Mounted on 1 sq. in. of a 4-layer PCB with 1 oz. copper thickness.

Figure 3. Pin Connections

PIN FUNCTION DESCRIPTIONS

Pin No.	Symbol	Description
1	VIN	Input voltage from battery. Place an input filter capacitor in close proximity to this pin.
2	DRV	Output voltage to provide a regulated voltage to the Power Switch gate driver.
3	RSTB	RSTB open drain output. Goes high impedance when the output is above 94% of its regulation level, after the delay set by the DELAY pin times out. Goes low when the output is below 92% of its regulation level (sensed on the FB signal)
4	GND	Battery return, and output voltage ground reference.
5	EN	This TTL compatible Enable input allows the direct connection of Battery as the enable signal. Grounding this input stops switching and reduces quiescent current draw to a minimum.
6	RDEPTH	Modulation depth adjustment for spread spectrum. Set with a resistor to GND.
7	RMOD	Modulation frequency adjustment for spread spectrum. Set with a resistor to GND.
8	COMP	Error Amplifier output, for tailoring transient response with external compensation components.
9	FB	Feedback input pin to program output voltage, and detect pre-charged or shorted output conditions.
10	DELAY	Delay adjust input. Connecting an external capacitor adjusts the delay for the RSTB function.
11	BST	Bootstrap input provides drive voltage higher than VIN to the N-channel Power Switch for optimum switch $R_{DS(on)}$ and highest efficiency.
12	SW	Switching node of the Regulator. Connect the output inductor and cathode of the freewheeling diode to this pin.
Exposed Pad		Connect to Pin 4 (electrical ground) and to a low thermal resistance path to the ambient temperature environment.

ELECTRICAL CHARACTERISTICS

($V_{IN} = 4.5\text{ V to }28\text{ V}$, $V_{EN} = 5\text{ V}$, $V_{BST} = V_{SW} + 3.0\text{ V}$, $C_{DRV} = 0.1\text{ }\mu\text{F}$, Min/Max values are valid for the temperature range $-40^{\circ}\text{C} \leq T_J \leq 150^{\circ}\text{C}$ unless noted otherwise, and are guaranteed by test, design or statistical correlation.)

GENERAL INFORMATION

INPUT VOLTAGE

An Undervoltage Lockout (UVLO) circuit monitors the input, and inhibits switching and resets the Soft-start circuit if there is insufficient voltage for proper regulation. The NCV890204 can regulate a 3.3 V output with input voltages above 4.5 V and a 5.0 V output with an input above 6.5 V.

The NCV890204 withstands input voltages up to 40 V.

To limit the power lost in generating the drive voltage for the Power Switch, the switching frequency is reduced by a factor of 2 when the input voltage exceeds the V_{IN} Frequency Foldback threshold V_{FLDUP} (see Figure 25). Frequency reduction is automatically terminated when the input voltage drops back below the V_{IN} Frequency Foldback threshold V_{FLDDN} .

Figure 25. NCV890204 Switching Frequency Reduction at High Input Voltage

ENABLE

The NCV890204 is designed to accept either a logic level signal or battery voltage as an Enable signal. EN low induces a 'sleep mode' which shuts off the regulator and minimizes its supply current to a couple of μA typically (I_{qSD}) by disabling all functions. Upon enabling, voltage is established at the DRV pin, followed by a soft-start of the switching regulator output.

SOFT-START

Upon being enabled or released from a fault condition, and after the DRV voltage is established, a soft-start circuit ramps the switching regulator error amplifier reference voltage to the final value. During soft-start, the average switching frequency is lower than its normal mode value (typically 2 MHz) until the output voltage approaches regulation.

SLOPE COMPENSATION

A fixed slope compensation signal is generated internally and added to the sensed current to avoid increased output voltage ripple due to bifurcation of inductor ripple current at duty cycles above 50%. The fixed amplitude of the slope compensation signal requires the inductor to be greater than a minimum value, depending on output voltage, in order to avoid sub-harmonic oscillations. For 3.3 V and 5 V output voltages, the recommended inductor value is 4.7 μH .

SHORT CIRCUIT FREQUENCY FOLDBACK

During severe output overloads or short circuits, the NCV890204 automatically reduces its switching frequency. This creates duty cycles small enough to limit the peak current in the power components, while maintaining the ability to automatically reestablish the output voltage if the overload is removed. If the current is still too high after the switching frequency folds back to 500 kHz, the regulator enters an auto-recovery burst mode that further reduces the dissipated power.

CURRENT LIMITING

Due to the ripple on the inductor current, the average output current of a buck converter is lower than the peak current setpoint of the regulator. Figure 26 shows – for a 4.7 μH inductor – how the variation of inductor peak current with input voltage affects the maximum DC current the NCV890204 can deliver to a load.

Figure 26. NCV890204 Load Current Capability with 4.7 μH Inductor

OUTPUT VOLTAGE SELECTION

The voltage output for the switcher is adjustable and can be set with a resistor divider. The FB reference for the switcher is 0.8 V.

Use the following equation:

$$R_{UPPER} = R_{LOWER} \frac{V_{OUT} - V_{FB}}{V_{FB}}$$

Some common setups are listed below:

Desired Output (V)	VREF (V)	R _{UPPER} (kΩ, 1%)	R _{LOWER} (kΩ, 1%)
1.2	0.8	100	200
1.5	0.8	100	115
1.8	0.8	100	80.6
2.5	0.8	100	47.5
3.3	0.8	100	32.4
5.0	0.8	100	19.1

A capacitor can be added in parallel to R_{Lower} for filtering the noise.

For example the below configurations can be used (we kept the RC constant):

- C = 4.7 pF, R_{Upper} = 100 kΩ and R_{Lower} = 19.1 kΩ.
- C = 4.7 nF, R_{Upper} = 100 Ω and R_{Lower} = 19.1 Ω.

RESET WITH ADJUSTABLE DELAY

The RSTB pin is pulled low as long as the voltage on the FB pin is lower than 92% (typical) of the reference voltage (which corresponds to the output voltage being lower than 92% of its regulation level). It is high impedance when the voltage goes above 94% (typical) of the regulation level, after a delay adjusted by the capacitor on the DELAY pin.

The capacitor is held at ground until the output enters regulation: C_{DELAY} is then quickly charged to the internal rail voltage (V_{RESU}), then discharged by the I_{delay} current until its voltage reaches the lower threshold V_{DELTH}. Only at this moment the RSTB pin voltage goes high, indicating the end of the Reset condition.

A small filtering delay (of duration t_{PG}) ensures that the RSTB signal doesn't toggle from high to low in case of high frequency noise when the output is in regulation.

A pull-up resistor is needed on the RSTB pin, as it features an open collector output, capable of sinking 1 mA minimum at 400 mV.

The RSTB pin is also pulled low in case of UVLO (V_{IN} below the UVLO threshold), TSD (temperature shutdown) or Disable (V_{EN} below the enable threshold) events.

Figure 27. Typical Operation of the Reset with Delay Function

SPREAD SPECTRUM

Spread spectrum modulates the 2 MHz internal oscillator frequency with a triangle wave to control the depth and frequency of modulation.

The modulation depth and modulation frequency are set by 2 external resistors to GND. The modulation frequency can be set from 5 kHz up to 50 kHz using a resistor from the RMOD pin to GND. The modulation depth can be set from 3% up to 30% of the nominal switching frequency using a resistor from the RDEPTH pin to GND. Please see the curves below for typical values:

Figure 28. Modulation Frequency vs. RMOD

Spread spectrum is automatically turned off when there is a short to GND or an open circuit on either the RMOD pin or the RDEPTH pin.

BOOTSTRAP

At the DRV pin an internal regulator provides a ground-referenced voltage to an external capacitor (C_{DRV}), to allow fast recharge of the external bootstrap capacitor (C_{BST}) used to supply power to the power switch gate driver. If the voltage at the DRV pin goes below the DRV UVLO Threshold V_{DRVSTB} switching is inhibited and the Soft-start circuit is reset, until the DRV pin voltage goes back up above V_{DRVSTT}.

Figure 29. Modulation Depth vs. RDEPTH

In order for the bootstrap capacitor to stay charged, the Switch node needs to be pulled down to ground regularly. In very light load condition, the NCV890204 skips switching cycles to ensure the output voltage stays regulated. When the skip cycle repetition frequency gets too low, the bootstrap voltage collapses and the regulator stops switching. Practically, this means that the NCV890204 needs a minimum load to operate correctly. Figure 30 shows the minimum current requirements for different input and output voltages.

The ‘Start Up minimum load’ is the minimum load required for the part to complete the soft start cycle. The ‘Operating minimum load’ is the minimum load required to maintain the part in proper regulation.

Minimum Load Criteria

Tests were performed on a typical part on one Evaluation board at room temperature.

Typical Minimum Load 5 V Out, L1 = 4.7 μH

Typical Minimum Load 5 V Out, L1 = 2.2 μH

Typical Minimum Load 3.3 V Out

Typical Minimum Load 3.7 V Out

Typical Minimum Load 5.5 V Out, L1 = 4.7 μH

Typical Minimum Load 5.5 V Out, L1 = 2.2 μH

Figure 30. Minimum Load Current with Different Input and Output Voltages

Figure 31. Output Voltage Detection

OUTPUT PRECHARGE DETECTION

Prior to Soft-start, the FB pin is monitored to ensure the SW voltage is low enough to have charged the external bootstrap capacitor (C_{BST}). If the FB pin is higher than V_{SSEN}, restart is delayed until the output has discharged. Figure 31 shows the IC starts to switch after the voltage on FB pin reaches V_{SSEN}, even the EN pin is high. After the IC is switching, the FB pin follows the soft starts reference to reach the final set point.

THERMAL SHUTDOWN

A thermal shutdown circuit inhibits switching, resets the Soft-start circuit, and removes DRV voltage if internal temperature exceeds a safe level. Switching is automatically restored when temperature returns to a safe level.

MINIMUM DROPOUT VOLTAGE

When operating at low input voltages, two parameters play a major role in imposing a minimum voltage drop across the regulator: the minimum off time (that sets the maximum duty cycle), and the on state resistance.

When operating in continuous conduction mode (CCM), the output voltage is equal to the input voltage multiplied by the duty ratio. Because the NCV890204 needs a sufficient bootstrap voltage to operate, its duty cycle cannot be 100%: it needs a minimum off time (t_{OFFmin}) to periodically re-fuel the bootstrap capacitor C_{BST} . This imposes a maximum duty ratio

$$D_{MAX} = 1 - t_{OFFmin} \cdot F_{SW(min)}$$

with the switching frequency being folded back down to $F_{SW(min)} = 500$ kHz to keep regulating at the lowest input voltage possible.

The drop due to the on-state resistance is simply the voltage drop across the Switch resistance R_{DSon} at the given output current:

$$V_{SWdrop} = I_{OUT} \cdot R_{DSon}$$

Which leads to the maximum output voltage in low V_{in} condition:

$$V_{OUT} = D_{MAX} \cdot V_{IN(min)} - V_{SWdrop}$$

EXPOSED PAD

The exposed pad (EPAD) on the back of the package must be electrically connected to the electrical ground (GND pin) for proper, noise-free operation.

DESIGN METHODOLOGY

The NCV890204 being a fixed-frequency regulator with the switching element integrated, is optimized for one value of inductor. This value is set to 4.7 μ H, and the slope compensation is adjusted for this inductor. The only components left to be designed are the input and output capacitor and the freewheeling diode. Please refer to the design spreadsheet www.onsemi.com NCV890204 page that helps with the calculation.

Output capacitor:

The minimum output capacitor value can be calculated based on the specification for output voltage ripple:

$$C_{OUTmin} = \frac{\Delta I_L}{8 \cdot \Delta V_{OUT} \cdot F_{SW}} \quad (\text{eq. 1})$$

With

- ΔI_L the inductor ripple current:

$$\Delta I_L = \frac{V_{OUT} \cdot \left(1 - \frac{V_{OUT}}{V_{IN}}\right)}{L \cdot F_{SW}} \quad (\text{eq. 2})$$

- ΔV_{OUT} the desired voltage ripple.

However, the ESR of the output capacitor also contributes to the output voltage ripple, so to comply with the requirement, the ESR cannot exceed R_{ESRmax} :

$$R_{ESRmax} = \frac{\Delta V_{OUT} \cdot L \cdot F_{SW}}{V_{OUT} \cdot \left(1 - \frac{V_{OUT}}{V_{IN}}\right)} \quad (\text{eq. 3})$$

Finally, the output capacitor must be able to sustain the ac current (or RMS ripple current):

$$I_{OUTac} = \frac{\Delta I_L}{2\sqrt{3}} \quad (\text{eq. 4})$$

Typically, with the recommended 4.7 μ H inductor, two ceramic capacitors of 10 μ F each in parallel give very good results.

Freewheeling diode:

The diode must be chosen according to its maximum current and voltage ratings, and to thermal considerations.

As far as max ratings are concerned, the maximum reverse voltage the diode sees is the maximum input voltage (with some margin in case of ringing on the Switch node), and the maximum forward current the peak current limit of the NCV890204, I_{LIM} .

The power dissipated in the diode is P_{Dloss} :

$$P_{Dloss} = I_{OUT} \cdot \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \cdot V_F + I_{DRMS} \cdot R_D \quad (\text{eq. 5})$$

with:

- I_{OUT} the average (dc) output current
- V_F the forward voltage of the diode
- I_{DRMS} the RMS current in the diode:

$$I_{DRMS} = \sqrt{(1 - D) \left(I_{OUT}^2 + \frac{\Delta I_L^2}{12} \right)} \quad (\text{eq. 6})$$

- R_D the dynamic resistance of the diode (extracted from the V/I curve of the diode in its datasheet).

Then, knowing the thermal resistance of the package and the amount of heatsinking on the PCB, the temperature rise corresponding to this power dissipation can be estimated.

Input capacitor:

The input capacitor must sustain the RMS input ripple current I_{INac} :

$$I_{INac} = \frac{\Delta I_L}{2} \sqrt{\frac{D}{3}} \quad (\text{eq. 7})$$

It can be designed in combination with an inductor to build an input filter to filter out the ripple current in the source, in order to reduce EMI conducted emissions.

For example, using a 4.7 μ H input capacitor, it is easy to calculate that an inductor of 200 nH will ensure that the input filter has a cut-off frequency below 200 kHz (low enough to attenuate the 2 MHz ripple).

Error Amplifier and Loop Transfer Function

The error amplifier is a transconductance type amplifier. The output voltage of the error amplifier controls the peak inductor current at which the power switch shuts off. The Current Mode control method employed allows the use of a simple, type II compensation to optimize the dynamic response according to system requirements.

Figure 32 shows the error amplifier with the compensation components and the voltage feedback divider.

Figure 32. Feedback Compensator Network Model

The transfer function from VOUT to VCOMP is the product of the feedback voltage divider and the error amplifier.

$$G_{\text{divider}}(s) = \frac{R_{\text{FB2}}}{R_{\text{FB1}} + R_{\text{FB2}}} \quad (\text{eq. 8})$$

$$G_{\text{err_amp}}(s) = g_m \cdot R_o \cdot \frac{1 + \frac{s}{\omega_Z}}{\left(1 + \frac{s}{\omega_{\text{pl}}}\right)\left(1 + \frac{s}{\omega_{\text{ph}}}\right)} \quad (\text{eq. 9})$$

$$\omega_Z = \frac{1}{R_{\text{COMP}} \cdot C_{\text{COMP}}} \quad (\text{eq. 10})$$

$$\omega_{\text{pl}} = \frac{1}{R_o \cdot C_{\text{COMP}}} \quad (\text{eq. 11})$$

$$\omega_{\text{ph}} = \frac{1}{R_{\text{COMP}} \cdot C_p} \quad (\text{eq. 12})$$

The output resistor R_o of the error amplifier is 1.4 M Ω and g_m is 1 mA/V. The capacitor C_p is for rejecting noise at high frequency and is integrated inside the IC with a value of 18 pF.

The power stage transfer function (from Vcomp to output) is shown below:

$$G_{\text{ps}}(s) = \frac{R_{\text{load}}}{R_i} \cdot \frac{1}{1 + \frac{R_{\text{load}} \cdot T_{\text{sw}}}{L} \cdot [M_c \cdot (1 - D) - 0.5]} \cdot \frac{1 + \frac{s}{\omega_Z}}{\left(1 + \frac{s}{\omega_p}\right)} \cdot F_h(s) \quad (\text{eq. 13})$$

$$\omega_Z = \frac{1}{R_{\text{resr}} \cdot C_{\text{out}}} \quad (\text{eq. 14})$$

$$\omega_p = \frac{1}{R_{\text{load}} \cdot C_{\text{out}}} + \frac{M_c \cdot (1 - D) - 0.5}{L \cdot C_{\text{out}} \cdot F_{\text{sw}}} \quad (\text{eq. 15})$$

where

$$M_c = 1 + \frac{S_e}{S_n} \quad (\text{eq. 16})$$

$$S_n = \frac{V_{\text{in}} - V_{\text{out}}}{L} \cdot R_i \quad (\text{eq. 17})$$

R_i represents the equivalent sensing resistor which has a value of 0.21 Ω , S_e is the compensation slope which is 500 kV/S, S_n is the slope of the sensing resistor current during on time. $F_h(s)$ represents the sampling effect from the current loop which has two poles at one half of the switching frequency:

$$F_h(s) = \frac{1}{1 + \frac{s}{\omega_n \cdot Q_p} + \frac{s^2}{\omega_n^2}} \quad (\text{eq. 18})$$

$$\omega_n = \pi \cdot F_{\text{sw}}$$

$$Q_p = \frac{1}{\pi \cdot [M_c \cdot (1 - D) - 0.5]} \quad (\text{eq. 19})$$

The total loop transfer function is the product of power stage and feedback compensation network.

$$G_{\text{loop}}(s) = G_{\text{divider}}(s) \cdot G_{\text{err_amp}}(s) \cdot G_{\text{ps}}(s) \quad (\text{eq. 20})$$

The bode plots of the open loop transfer function will show the gain and phase margin of the system. The compensation network is designed to make sure the system has enough phase margin and bandwidth.

Design of the Compensation Network

The function of the compensation network is to provide enough phase margin at crossover frequency to stabilize the system as well as to provide high gain at low frequency to eliminate the steady state error of the output voltage. Please refer to the design spreadsheet www.onsemi.com NCV890204 page that helps with the calculation.

The design steps will be introduced through an example.

Example:

$V_{\text{in}} = 15.5$ V, $V_{\text{out}} = 3.3$ V, $R_{\text{load}} = 1.65$ Ω , $I_{\text{out}} = 2$ A, $L = 4.7$ μ H, $C_{\text{out}} = 20$ μ F ($R_{\text{resr}} = 7$ m Ω)

The reference voltage of the feedback signal is 0.8 V and to meet the minimum load requirements, select $R_{\text{FB1}} = 100$ Ω , $R_{\text{FB2}} = 31.6$ Ω .

From the specification, the power stage transfer function can be plotted as below:

Figure 33. Power Stage Bode Plots

The crossover frequency is chosen to be $F_c = 70 \text{ kHz}$, the power stage gain at this frequency is -5.3 dB (0.54) from calculation. Then the gain of the feedback compensation network must be 5.3 dB . Next is to decide the locations of one zero and one pole of the compensator. The zero is to provide phase boost at the crossover frequency and the pole is to reject the noise of high frequency. In this example, a zero is placed at $1/10$ of the crossover frequency and a pole is placed at $1/5$ of the switching frequency ($F_{sw} = 2 \text{ MHz}$): $F_z = 7000 \text{ Hz}$, $F_p = 400000 \text{ Hz}$,

R_{COMP} , C_{COMP} and C_p can be calculated from the following equations:

$$R_{COMP} = \frac{F_p \cdot g_m}{(F_p - F_z) \cdot |G_{ps}(F_c)|} \cdot \frac{V_{out}}{V_{ref}} \cdot \frac{\sqrt{1 + \left(\frac{F_c}{F_p}\right)^2}}{\sqrt{1 + \left(\frac{F_z}{F_c}\right)^2}} \quad (\text{eq. 21})$$

$$C_{COMP} = \frac{1}{2\pi \cdot F_z \cdot R_{COMP}} \quad (\text{eq. 22})$$

$$C_p = \frac{1}{2\pi \cdot F_p \cdot R_{COMP}} \quad (\text{eq. 23})$$

Note: there is an 18 pF capacitor at the output of the OTA integrated in the IC, and if a larger capacitor needs to be used, subtract this value from the calculated C_p . Figure 34 shows C_p is split into two capacitors. C_{int} is the 18 pF in the IC. C_{ext} is the extra capacitor added outside the IC.

From the calculation:

$$R_{COMP} = 7.7 \text{ K}\Omega, C_{COMP} = 3 \text{ nF}, C_p = 41 \text{ pF}$$

So the feedback compensation network is as below:

Figure 34. Example of the Feedback Compensation Network

Figure 35 shows the bode plot of the OTA compensator

Figure 35. Bode Plot of the OTA Compensator

The total loop bode plot is as below:

Figure 36. Bode Plot of the Total Loop

The crossover frequency is at 70 KHz and phase margin is 75 degrees.

PCB LAYOUT RECOMMENDATION

As with any switching power supplies, there are some guidelines to follow to optimize the layout of the printed circuit board for the NCV890204. However, because of the high switching frequency extra care has to be taken.

- Minimize the area of the power current loops:
 - ◆ Input capacitor → NCV890204 switch → Inductor → output capacitor → return through Ground

- ◆ Freewheeling diode → inductor → Output capacitor → return through ground
- Minimize the length of high impedance signals, and route them far away from the power loops:
 - ◆ Feedback trace
 - ◆ Comp trace

ORDERING INFORMATION

Device	Package	Shipping†
NCV890204MWR2G	DFN12 with wettable flanks (Pb-Free)	3000 / Tape & Reel

†For information on tape and reel specifications, including part orientation and tape sizes, please refer to our Tape and Reel Packaging Specifications Brochure, BRD8011/D.

PACKAGE DIMENSIONS

DFN12, 4x4, 0.65P
CASE 506CE
ISSUE O

NOTES:

1. DIMENSIONS AND TOLERANCING PER ASME Y14.5M, 1994.
2. CONTROLLING DIMENSION: MILLIMETERS.
3. DIMENSION b APPLIES TO PLATED TERMINAL AND IS MEASURED BETWEEN 0.15 AND 0.30 MM FROM TERMINAL.
4. COPLANARITY APPLIES TO THE EXPOSED PAD AS WELL AS THE TERMINALS.

MILLIMETERS		
DIM	MIN	MAX
A	0.80	1.00
A1	0.00	0.05
A3	0.20	REF
b	0.25	0.35
D	4.00	BSC
D2	3.30	3.50
E	4.00	BSC
E2	2.40	2.60
e	0.65	BSC
K	0.20	---
L	0.30	0.50
L1	---	0.15
