

## FEATURES

- Low skew
- Extended 100E  $V_{EE}$  range of  $-4.2V$  to  $-5.5V$
- Guaranteed skew limits
- Differential design
- $V_{BB}$  output
- Enable input
- Fully compatible with industry standard 10KH, 100K I/O levels
- 75K $\Omega$  input pulldown resistors
- Fully compatible with ON Semiconductor MC10E/100E111
- Available in 28-pin PLCC package

## DESCRIPTION

The SY10/100E111 are low skew 1-to-9 differential drivers designed for clock distribution in new, high-performance ECL systems. They accept one differential or single-ended input, with  $V_{BB}$  used for single-ended operation. The signal is fanned out to nine identical differential outputs. An enable input is also provided such that a logic HIGH disables the device by forcing all Q outputs LOW and all /Q outputs HIGH.

The device is specifically designed and produced for low skew. The interconnect scheme and metal layout are carefully optimized for minimal gate-to-gate skew within the device. Wafer characterization and process control ensure consistent distribution of propagation delay from lot to lot. Since the E111 shares a common set of "basic" processing with the other members of the ECLinPS™ family, wafer characterization at the point of device personalization allows for tighter control of parameters, including propagation delay.

To ensure that the skew specification is met, it is necessary that both sides of the differential output are terminated into 50 $\Omega$ , even if only one side is being used. In most applications, all nine differential pairs will be used and, therefore, terminated. In the case where fewer than nine pairs are used, it is necessary to terminate at least the output pairs on the same package side (i.e. sharing the same  $V_{CCO}$  as the pair(s) being used on that side) in order to maintain minimum skew.

The  $V_{BB}$  output is intended for use as a reference voltage for single-ended reception of ECL signals to that device only. When using  $V_{BB}$  for this purpose, it is recommended that  $V_{BB}$  is decoupled to  $V_{CC}$  via a 0.01 $\mu F$  capacitor.

## BLOCK DIAGRAM

## PIN NAMES

Pin	Function
IN, /IN	Differential Input Pair
/EN	Enable Input
Q0, /Q0 — Q8, /Q8	Differential Outputs
$V_{BB}$	$V_{BB}$ Output
$V_{CCO}$	$V_{CC}$ to Output

**Notes:**

- The differential propagation delay is defined as the delay from the crossing points of the differential input signals to the crossing point of the differential output signals.
- The single-ended propagation delay is defined as the delay from the 50% point of the input signal to the 50% point of the output signal.
- Enable is defined as the propagation delay from the 50% point of a **negative** transition on /EN to the 50% point of a **positive** transition on Q (or a negative transition on /Q). Disable is defined as the propagation delay from the 50% point of a **positive** transition on /EN to the 50% point of a **negative** transition on Q (or a positive transition on /Q).
- The within-device skew is defined as the worst case difference between any two similar delay paths within a single device.
- The set-up time is the minimum time that /EN must be asserted prior to the next transition of /IN/IN to prevent an output response greater than  $\pm 75\text{mV}$  to that /IN/IN transition (see Figure 1).
- The hold time is the minimum time that /EN must remain asserted after a negative going IN or a positive going /IN to prevent an output response greater than  $\pm 75\text{mV}$  to that IN, /IN transition (see Figure 2).
- The release time is the minimum time that /EN must be de-asserted prior to the next IN, /IN transition to ensure an output response that meets the specified IN to Q propagation delay and output transition times (see Figure 3).
- $V_{PP}$  (min.) is defined as the minimum input differential voltage which will cause no increase in the propagation delay. The  $V_{PP}$  (min.) is AC limited for the E111, as a differential input as low as 50mV will still produce full ECL levels at the output.
- $V_{CMR}$  is defined as the range within which the  $V_{IH}$  level may vary, with the device still meeting the propagation delay specification. The  $V_{IL}$  level must be such that the peak-to-peak voltage is less than 1.0V and greater than or equal to  $V_{PP}$  (min.).
