Operation and Application Description

Input Capacitor

To limit the voltage drop on the input supply caused by transient inrush current when the switch turns on into discharge load capacitor; a capacitor must be placed between the VIN and GND pins. A high-value C_{IN} capacitor can be used to reduce the voltage drop in high-current applications.

Output Capacitor

An output capacitor should be placed between the VOUT and GND pins. This capacitor prevents parasitic board inductance from forcing VOUT below ground when the switch is on. This capacitor also prevents reverse inrush current from creating a voltage spike that could damage the device in the case of a VOUT short.

Fault Reporting

Upon the detection of an over-voltage, over-current, or over-temperature condition, the FLAGB signals the fault by activating LOW.

Under-Voltage Lockout (UVLO)

The under-voltage lockout turns the switch off if the input voltage drops below the lockout threshold. With the ON pin active, the input voltage rising above the UVLO threshold releases the lockout and enables the switch.

Over-Voltage Lockout (OVLO)

The OVLO pin sets the over-voltage lockout trip point with a resistor-divider network. OVLO adjustment is set by R1 and R2 and is compared to $1.2 V - V_{IN} \times R2 / (R1+R2) > 1.2 V$. when $V_{IN} > V_{OVLO}$ the switch turns off to ensure protection to devices connected to VOUT. A 1 MΩ or larger resistor is recommended on R1 to reduce standby power consumption. To use the default values of 5.8 V for V_{OVLO} , connect the OVLO pin directly to GND.

Package Specific Dimensions

D	E	X	Y
1.300±0.030	1.050±0.030	0.325	0.250

Reverse-Current Blocking (RCB)

The reverse-current blocking feature protects the input source against current flow from output to input. When the load switch is OFF, no current flows from the output to input.

Thermal Shutdown (TSD)

Thermal shutdown protects the die from internally or externally generated excessive temperature. During an over-temperature condition, the switch is turned off. The switch automatically turns on again if the temperature of the die drops below the threshold temperature.

Current Limit

The current limit ensures that the current flow through the switch doesn't exceed a maximum value, which can damage the device. If the current flow through the switch exceeds the trip point, the switch turns off and enters the blanking time. After the blanking time, the switch is re-enabled and checks if the fault still exists.

Board Layout

For best performance, all traces should be as short as possible. The input and output capacitors should be placed close to the device to minimize the effect that parasitic trace inductance may have on normal and short-circuit operation. Using wide traces for VIN, VOUT, GND minimizes parasitic electrical effects along with minimizing the case-to-ambient thermal impedance.
