

LMV71x-N Low-Power, RRIO Operational Amplifiers With High Output Current Drive and Shutdown Option

1 Features

- Low Offset Voltage: 3 mV (Maximum)
- Gain-Bandwidth Product: 5 MHz (Typical)
- Slew Rate: 5 V/ μ s (Typical)
- Space-Saving Packages: 5-Pin and 6-Pin SOT-23
- Turnon Time From Shutdown: <10 μ s
- Industrial Temperature Range: -40°C to 85°C
- Supply Current in Shutdown Mode: 0.2 μ A (Typical)
- Ensured 2.7-V and 5-V Performance
- Unity Gain Stable
- Rail-to-Rail Input and Output
- Capable of Driving 600- Ω Load

2 Applications

- Wireless Phones
- GSM, TDMA, and CDMA Power Amp Controls
- AGC and RF Power Detectors
- Temperature Compensation
- Wireless LAN
- Bluetooth
- HomeRF

3 Description

The LMV710-N, LMV711-N, and LMV715-N are BiCMOS operational amplifiers with a CMOS input stage. These devices have greater than RR input common mode voltage range, rail-to-rail output and high output current drive. They offer a bandwidth of 5 MHz and a slew rate of 5 V/ μ s.

On the LMV711 and LMV715, a separate shutdown pin can be used to disable the device and reduces the supply current to 0.2 μ A (typical). They also feature a turnon time of less than 10 μ s. It is an ideal solution for power-sensitive applications, such as cellular phone, pager, palm computer, and so forth. In addition, once the LMV715 is in shutdown the output is tri-stated.

The LMV710 is offered in the space-saving, 5-pin SOT-23 package. The LMV711 and LMV715 are offered in the space saving 6-pin SOT-23 package.

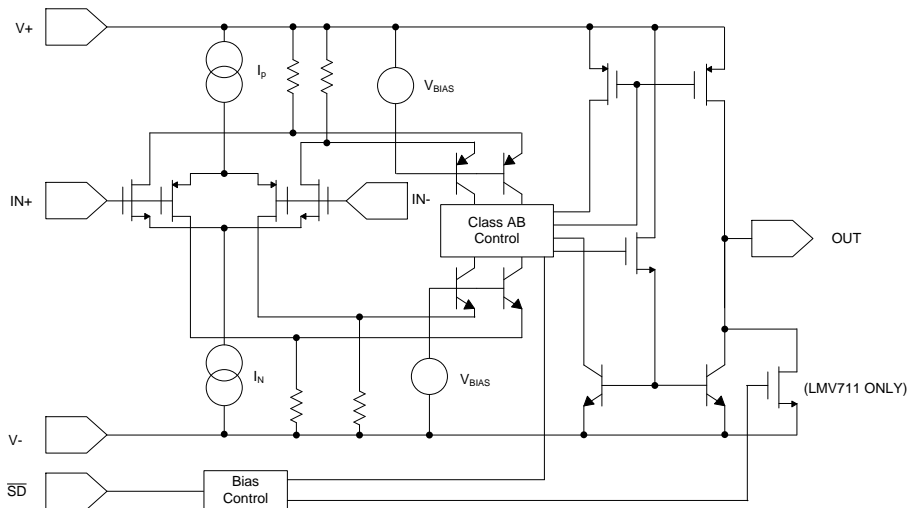

The LMV71x-N devices are designed to meet the demands of low power, low cost, and small size required by cellular phones and similar battery-powered portable electronics.

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) If Military/Aerospace specified devices are required, please contact the Texas Instruments Sales Office/ Distributors for availability and specifications.
- (3) Shorting circuit output to V⁺ will adversely affect reliability.
- (4) Shorting circuit output to V⁻ will adversely affect reliability.
- (5) The maximum power dissipation is a function of T_{J(MAX)}, R_{θJA}, and T_A. The maximum allowable power dissipation at any ambient temperature is P_D = (T_{J(MAX)} - T_A) / R_{θJA}. All numbers apply for packages soldered directly into a PCB.

7 Detailed Description

7.1 Overview

The LMV710-N, LMV711-N, and LMV715-N operational amplifiers provide a CMOS input stage, high current drive rail-to-rail output, and a greater than RR input common mode voltage range. They also provide a slew rate of 5 V/ μ s at a bandwidth of 5 MHz.

7.2 Functional Block Diagram

Copyright © 2016, Texas Instruments Incorporated

7.3 Feature Description

7.3.1 Supply Bypassing

The application circuits in this datasheet do not show the power supply connections and the associated bypass capacitors for simplification. When the circuits are built, it is always required to have bypass capacitors. Ceramic disc capacitors (0.1 μ F) or solid tantalum (1 μ F) with short leads, and located close to the IC are usually necessary to prevent interstage coupling through the power supply internal impedance. Inadequate bypassing will manifest itself by a low frequency oscillation or by high frequency instabilities. Sometimes, a 10- μ F (or larger) capacitor is used to absorb low frequency variations and a smaller 0.1- μ F disc is paralleled across it to prevent any high frequency feedback through the power supply lines.

7.3.2 Shutdown Mode

The LMV711 and LMV715 have a shutdown pin. To conserve battery life in portable applications, they can be disabled when the shutdown pin voltage is pulled low. For LMV711 during shutdown mode, the output stays at about 50 mV from the lower rail, and the current drawn from the power supply is 0.2 μ A (typical). This makes the LMV711 an ideal solution for power sensitive applications. For the LMV715 during shutdown mode, the output is tri-stated.

The shutdown pin must never be left unconnected. In applications where shutdown operation is not required and the LMV711 or LMV715 is used, the shutdown pin must be connected to V^+ . Leaving the shutdown pin floating results in an undefined operation mode and the device may oscillate between shutdown and active modes.

Feature Description (continued)

7.3.3 Rail-to-Rail Input

The rail-to-rail input is achieved by using paralleled PMOS and NMOS differential input stages (see [Functional Block Diagram](#)). When the common mode input voltage changes from ground to the positive rail, the input stage goes through three modes. First, the NMOS pair is cutoff and the PMOS pair is active. At around 1.4 V, both PMOS and NMOS pairs operate, and finally the PMOS pair is cutoff and NMOS pair is active. Because both input stages have their own offset voltage (V_{OS}), the offset of the amplifier becomes a function of the common-mode input voltage (see [Figure 33](#) and [Figure 34](#) in [Typical Characteristics](#)).

As shown in the curve, the V_{OS} has a crossover point at 1.4 V above V^- . Proper design must be done in both DC- and AC-coupled applications to avoid problems. For large input signals that include the V_{OS} crossover point in their dynamic range, it causes distortion in the output signal. One way to avoid such distortion is to keep the signal away from the crossover point. For example, in a unity-gain buffer configuration and with $V_S = 5$ V, a 3-V peak-to-peak signal center at 2.5 V contains input-crossover distortion. To avoid this, the input signal must be centered at 3.5 V instead. Another way to avoid large signal distortion is to use a gain of -1 circuit which avoids any voltage excursions at the input terminals of the amplifier (see [Figure 35](#)). In this circuit, the common-mode DC voltage (V_{CM}) can be set at a level away from the V_{OS} crossover point.

Figure 35. Inverting Configuration

When the input is a small signal and this small signal falls inside the V_{OS} transition range, the gain, CMRR and some other parameters is degraded. To resolve this problem, the small signal must be placed such that it avoids the V_{OS} crossover point.

To achieve maximum output swing, the output must be biased at mid-supply. This is normally done by biasing the input at mid-supply. But with supply voltage range from 2 V to 3.4 V, the input of the op amp must not be biased at mid-supply because of the transition of the V_{OS} . [Figure 36](#) shows an example of how to get away from the V_{OS} crossover point and maintain a maximum swing with a 2.7-V supply. [Figure 37](#) shows the waveforms of V_{IN} and V_{OUT} .

Figure 36. Vout biasing Example

Feature Description (continued)

Figure 37. Vout biasing Output Results

The inputs can be driven 300 mV beyond the supply rails without causing phase reversal at the output. However, the inputs must not be allowed to exceed the maximum ratings.

7.4 Device Functional Modes
7.4.1 Compensation of Input Capacitance

In the application (Figure 38) where a large feedback resistor is used, the feedback resistor can react with the input capacitance of the op amp and introduce an additional pole to the close loop frequency response.

Figure 38. Cancelling the Effect of Input Capacitance

Device Functional Modes (continued)

This pole occurs at frequency f_p with Equation 1.

$$f_p = \frac{1}{2\pi(R_{IN} \parallel R_F)C_{IN}} \quad (1)$$

Any stray capacitance due to external circuit board layout, any source capacitance from transducer or photodiode connected to the summing node is added to the input capacitance. If f_p is less than or close to the unity-gain bandwidth (5 MHz) of the op amp, the phase margin of the loop is reduced and can cause the system to be unstable.

To avoid this problem, make sure that f_p occurs at least 2 octaves beyond the expected -3 dB frequency corner of the close loop frequency response. If not, a feedback capacitor C_F can be placed in parallel with R_F such that Equation 2.

$$\frac{1}{2\pi R_F C_F} = \frac{1}{2\pi(R_{IN} \parallel R_F)(C_F + C_{IN})} \quad (2)$$

The paralleled R_F and C_F introduce a zero, which cancels the effect from the pole.

7.4.2 Capacitive Load Tolerance

The LMV71x-N can directly drive 200 pF in unity-gain without oscillation. The unity-gain follower is the most sensitive configuration to capacitive loading. Direct capacitive loading reduces the phase margin of amplifiers. The combination of the amplifier's output impedance and the capacitive load induces phase lag. This results in either an underdamped pulse response or oscillation. To drive a heavier capacitive load, circuit in Figure 39 can be used.

Figure 39. Indirectly Driving a Capacitive Load Using Resistive Isolation

In Figure 39, the isolation resistor R_{ISO} and the load capacitor C_L form a pole to increase stability by adding more phase margin to the overall system. The desired performance depends on the value of R_{ISO} . The bigger the R_{ISO} resistor value, the more stable V_{OUT} is. But the DC accuracy is not great when the R_{ISO} gets bigger. If there were a load resistor in Figure 39, the output would be voltage divided by R_{ISO} and the load resistor.

The circuit in Figure 40 is an improvement to the one in Figure 39 because it provides DC accuracy as well as AC stability. In this circuit, R_F provides the DC accuracy by using feed-forward techniques to connect V_{IN} to R_L . C_F and R_{ISO} serve to counteract the loss of phase margin by feeding the high-frequency component of the output signal back to the inverting input of the amplifier, thereby preserving phase margin in the overall feedback loop. Increased capacitive drive is possible by increasing the value of C_F . This in turn slows down the pulse response.

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The LMV71x family of amplifiers features low voltage, low power, and rail-to-rail output operational amplifiers designed for low-voltage portable applications.

8.2 Typical Applications

8.2.1 High-Side Current-Sensing

Figure 41. High-Side, Current-Sensing Schematic

8.2.1.1 Design Requirements

The high-side, current-sensing circuit (Figure 41) is commonly used in a battery charger to monitor charging current to prevent over charging. A sense resistor R_{SENSE} is connected to the battery directly. This system requires an op amp with rail-to-rail input. The LMV71x are ideal for this application because its common-mode input range goes up to the rail.

8.2.1.2 Detailed Design Procedure

As seen in (Figure 41), the I_{CHARGE} current flowing through sense resistor R_{SENSE} develops a voltage drop equal to V_{SENSE} . The voltage at the negative sense point is now less than the positive sense point by an amount proportional to the V_{SENSE} voltage.

The low-bias currents of the LMV71x cause little voltage drop through R_2 , so the negative input of the LMV71x amplifier is at essentially the same potential as the negative sense input.

The LMV71x detects this voltage error between its inputs and servo the transistor base to conduct more current through Q1, increasing the voltage drop across R_1 until the LMV71x inverting input matches the noninverting input. At this point, the voltage drop across R_1 now matches V_{SENSE} .

I_G , a current proportional to I_{CHARGE} , flows according to Equation 3.

Typical Applications (continued)

$$I_G = V_{RSENSE} / R_1 = (R_{SENSE} \times I_{CHARGE}) / R_1 \tag{3}$$

I_G also flows through the gain resistor R_3 developing a voltage drop equal to Equation 4.

$$V_3 = I_G \times R_3 = (V_{RSENSE} / R_1) \times R_3 = ((R_{SENSE} \times I_{CHARGE}) / R_2) \times R_3 \tag{4}$$

$$V_{OUT} = (R_{SENSE} \times I_{CHARGE}) \times G$$

where

- $G = R_3 / R_1$ (5)

The other channel of the LMV71x may be used to buffer the voltage across R_3 to drive the following stages.

8.2.2 Peak Detector

Figure 43. Peak Detector

8.2.2.1 Design Requirements

A peak detector outputs a DC voltage equal to the peak value of the applied AC signal. Peak detectors are used in many applications, such as test equipment, measurement instrumentation, ultrasonic alarm systems, and so forth. Figure 43 shows the schematic diagram of a peak detector using LMV71x-N. This peak detector basically consists of a clipper, a parallel RC network, and a voltage follower.

Typical Applications (continued)

8.2.2.2 Detailed Design Procedure

An AC voltage source applied to V_{IN} charges capacitor C1 to the peak of the input. Diode D1 conducts positive half cycles, charging C1 to the waveform peak. Including D1 inside the feedback loop of the amplifier removes the voltage drop of D1 and allows an accurate peak detection of V_{IN} on C1. When the input waveform falls below the DC peak stored on C1, D1 is reverse biased. The low input bias current of A1 and the reverse biasing of D1 limits current leakage from C1. As a result, C1 retains the peak value even as the waveform drops to zero. A2 further isolates the peak value on C1 while completing the peak detector circuit by operating as a voltage follower and reporting the peak voltage of C1 at its output.

R5 and C1 are properly selected so that the capacitor is charged rapidly to V_{IN} . During the holding period, the capacitor slowly discharge through C1, through leakage of the capacitor and the reverse-biased diode, or op amp bias currents. In any cases the discharging time constant is much larger than the charge time constant. And the capacitor can hold its voltage long enough to minimize the output ripple.

Resistors R2 and R3 limit the current into the inverting input of A1 and the noninverting input of A2 when power is disconnected from the circuit. The discharging current from C1 during power off may damage the input circuitry of the op amps.

The peak detector is reset by applying a positive pulse to the reset transistor. The charge on the capacitor is dumped into ground, and the detector is ready for another cycle.

The maximum input voltage to this detector must be less than $(V^+ - V_D)$, where V_D is the forward voltage drop of the diode. Otherwise, the input voltage must be scaled down before applying to the circuit.

8.2.3 GSM Power Amplifier Control Loop

Figure 44. GSM P.A. Control Loop

8.2.3.1 Design Requirements

The control loop in Figure 44 controls the output power level of a GSM mobile phones. The control loop is used to avoid intermodulation of Base Station receivers, to prevent intermodulation with other mobile phones, and to minimize power consumption depending on the distance between mobile and base station

Typical Applications (continued)

8.2.3.2 Detailed Design Procedure

There are four critical sections in the GSM Power Amplifier Control Loop. The class-C R_F power amplifier provides amplification of the R_F signal. A directional coupler couples small amount of R_F energy from the output of the R_F P. A. to an envelope detector diode. The detector diode senses the signal level and rectifies it to a DC level to indicate the signal strength at the antenna. An op amp is used as an error amplifier to process the diode voltage and ramping voltage. This loop control the power amplifier gain through the op amp and forces the detector diode voltage and ramping voltage to be equal. Power control is accomplished by changing the ramping voltage.

The LMV71x-N are well suited as an error amplifier in this application. The LMV711 or LMV715 have an extra shutdown pin to switch the op amp to shutdown mode. In shutdown mode, the LMV711 or LMV715 consume very low current. The LMV711 provides a ground voltage to the power amplifier control pin V_{PC} . Therefore, the power amplifier can be turned off to save battery life. The LMV715 output is tri-stated when in shutdown.

9 Power Supply Recommendations

For proper operation, the power supplies must be properly decoupled. For decoupling the supply lines, TI recommends that 10-nF capacitors be placed as close as possible to the power supply pins of the operational amplifier. For single supply, place a capacitor between V^+ and V^- supply leads. For dual supplies, place one capacitor between V^+ and ground, and one capacitor between V^- and ground.

10 Layout

10.1 Layout Guidelines

To properly bypass the power supply, several locations on a printed-circuit board must be considered. A 6.8- μ F or greater tantalum capacitor must be placed at the point where the power supply for the amplifier is introduced onto the board. Another 0.1- μ F ceramic capacitor must be placed as close as possible to the power supply pin of the amplifier. If the amplifier is operated in a single power supply, only the V^+ pin requires a bypass with a 0.1- μ F capacitor. If the amplifier is operated in a dual power supply, both V^+ and V^- pins must be bypassed. It is good practice to use a ground plane on a printed-circuit board to provide all components with a low inductive ground connection.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.
