# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

__General Description

The MAX17126/MAX17126A generate all the supply rails for thin-film transistor liquid-crystal display (TFT LCD) TV panels operating from a regulated 12 V input. They include a step-down and a step-up regulator, a positive and a negative charge pump, an operational amplifier, a high-accuracy high-voltage gamma reference, and a high-voltage switch control block. The MAX17126/ MAX17126A can operate from input voltages from 8 V to 16.5 V and is optimized for an LCD TV panel running directly from 12 V supplies.
The step-up and step-down switching regulators feature internal power MOSFETs and high-frequency operation allowing the use of small inductors and capacitors, resulting in a compact solution. The step-up regulator provides TFT source driver supply voltage, while the step-down regulator provides the system with logic supply voltage. Both regulators use fixed-frequency currentmode control architectures, providing fast load-transient response and easy compensation. A current-limit function for internal switches and output-fault shutdown protects the step-up and step-down power supplies against fault conditions. The MAX17126/MAX17126A provide soft-start functions to limit inrush current during startup. In addition, the MAX17126/MAX17126A integrate a control block that can drive an external p-channel MOSFET to sequence power to source drivers.
The positive and negative charge-pump regulators provide TFT gate-driver supply voltages. Both output voltages can be adjusted with external resistive voltagedividers. A logic-controlled, high-voltage switch block allows the manipulation of the positive gate-driver supply.
The MAX17126/MAX17126A include one high-current operational amplifier designed to drive the LCD backplane (VCOM). The amplifier features high output current $( \pm 200 \mathrm{~mA})$, fast slew rate $(45 \mathrm{~V} / \mu \mathrm{s})$, wide bandwidth $(20 \mathrm{MHz})$, and rail-to-rail outputs.
Also featured in the MAX17126/MAX17126A is a highaccuracy, high-voltage adjustable reference for gamma correction.
The MAX17126/MAX17126A are available in a small (7mm $\times 7 \mathrm{~mm}$ ), ultra-thin ( 0.8 mm ), 48-pin thin QFN package and operate over the $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ temperature range.

## Applications

LCD TV Panels

- 8.0V to 16.5 V IN Supply-Voltage Range
- Selectable Frequency (500kHz/750kHz)
- Current-Mode Step-Up Regulator

Fast Load-Transient Response
High-Accuracy Output Voltage (1.0\%)
Built-In 20V, 4.2A, $100 \mathrm{~m} \Omega$ MOSFET
High Efficiency
Adjustable Soft-Start
Adjustable Current Limit
Low Duty-Cycle Operation (13.2VIN-13.5V AVDD)

- Current-Mode Step-Down Regulator

Fast Load-Transient Response
Built-In 20V, 3.2A, 100m $\Omega$ MOSFET
High Efficiency
3ms Internal Soft-Start

- Adjustable Positive Charge-Pump Regulator
- Adjustable Negative Charge-Pump Regulator
- Integrated High-Voltage Switch with Adjustable Turn-On Delay
- High-Speed Operational Amplifier $\pm 200 \mathrm{~mA}$ Short-Circuit Current 45V/ $\mu$ s Slew Rate
- High-Accuracy Reference for Gamma Buffer $\pm 1 \%$ Feedback Voltage Up to 30mA Load Current Low-Dropout Voltage 0.5 V at 60 mA
- External p-Channel Gate Control for AVDD Sequencing
- PGOOD Comparator
- Input Undervoltage Lockout and ThermalOverload Protection
- 48-Pin, 7mm x 7mm, Thin QFN Package

Ordering Information

| PART | TEMP RANGE | PIN-PACKAGE |
| :--- | :--- | :---: |
| MAX17126ETM + | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 48 Thin QFN-EP* |
| MAX17126AETM + | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 48 Thin QFN-EP* |

+Denotes a lead(Pb)-free/RoHS-compliant package.
*EP = Exposed pad.

Pin Configuration appears at end of data sheet.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS

(Circuit of Figure 1, VINVL $=\mathrm{V}_{\mathrm{IN}}=12 \mathrm{~V}, \mathrm{VVOP}=\mathrm{VVREF}_{-} \mathrm{I}=15 \mathrm{~V}, \mathbf{T}_{\mathbf{A}}=\mathbf{0}^{\circ} \mathbf{C}$ to $+85^{\circ} \mathrm{C}$. Typical values are at $\mathrm{T}=+25^{\circ} \mathrm{C}$, unless otherwise noted.)

Note 1: When the step-down inductor is in continuous conduction ( $\mathrm{EN}=\mathrm{VL}$ or heavy load), the output voltage has a DC regulation level lower than the error comparator threshold by $50 \%$ of the output voltage ripple. In discontinuous conduction (EN = GND with light load), the output voltage has a DC regulation level higher than the error comparator threshold by $50 \%$ of the output voltage ripple.
Note 2: Disables boost switching if either GD_I or VOP exceeds the threshold. Switching resumes when no threshold is exceeded.
Note 3: Specifications to $\mathrm{TA}_{\mathrm{A}}=-40^{\circ} \mathrm{C}$ are guaranteed by design, not production tested.

# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

| PIN | NAME | FUNCTION |
| :---: | :---: | :---: |
| 1 | VREF_I | Gamma Reference Input |
| 2 | VOP | Operational Amplifier Power Supply |
| 3 | OGND | Operational Amplifier Power Ground |
| 4 | OPP | Operational Amplifier Noninverting Input |
| 5 | OPN | Operational Amplifier Inverting Input |
| 6 | OPO | Operational Amplifier Output |
| 7 | PGOOD | Input voltage power-good open-drain output pulled high to VL or 3.3V through 10k $\Omega$ resistor. |
| 8 | GVOFF | High-Voltage Switch-Control Block Timing Control Input. See the High-Voltage Switch Control section for details. |
| 9 | EN | Enable Input. Enable is high, turns on step-up converter and positive charge pump. |
| 10 | FB2 | Step-Down Regulator Feedback Input. Connect FB2 to GND to select the step-down converter's 3.3V fixed mode. For adjustable mode, connect FB2 to the center of a resistive voltage-divider between the step-down regulator output (OUT) and GND to set the step-down regulator output voltage. Place the resistive voltage-divider within 5 mm of FB2. |
| 11 | OUT | Step-Down Regulator Output Voltage Sense. Connect OUT to step-down regulator output. |
| 12 | N.C. | Not Connected |
| 13, 14 | LX2 | Step-Down Regulator Switching Node. LX2 is the source of the internal n-channel MOSFET connected between IN2 and LX2. Connect the inductor and Schottky catch diode to both LX2 pins and minimize the trace area for lowest EMI. |
| 15 | BST | Step-Down Regulator Bootstrap Capacitor Connection. Power supply for high-side gate driver. Connect a $0.1 \mu \mathrm{~F}$ ceramic capacitor from BST to LX2. |
| 16, 17 | IN2 | Step-Down Regulator Power Input. Drain of the internal n-channel MOSFET connected between IN2 and LX2. |
| 18, 44 | GND | Analog Ground |
| 19 | VDET | Voltage-Detector Input. Connects VDET to the center of a resistor voltage-divider between input voltage and GND to set the trigger point of PGOOD. |
| 20 | INVL | Internal 5V Linear Regulator and the Startup Circuitry Power Supply. Bypass VINVL to GND with $0.22 \mu \mathrm{~F}$ close to the IC. |
| 21 | VL | 5V Internal Linear Regulator Output. Bypass VL to GND with $1 \mu \mathrm{~F}$ minimum. Provides power for the internal MOSFET driving circuit, the PWM controllers, charge-pump regulators, logic, and reference and other analog circuitry. Provides 25 mA load current when all switching regulators are enabled. VL is active whenever input voltage is high enough. |
| 22 | FSEL | Frequency Select Pin. Connect FSEL to VL or INVL or float FSEL pin for 750 kHz operation. Connect to GND for 500 kHz operation. |
| 23 | CLIM | Boost Current-Limit Setting Input. Connects a resistor from CLIM to GND to set current limit for boost converter. |
| 24 | SS | Soft-Start Input. Connects a capacitor from SS to GND to set the soft-start time for the step-up converter. A $5 \mu \mathrm{~A}$ current source starts to charge Css when GD is done. See the Step-Up Regulator External pMOS Pass Switch section for description. SS is internally pulled to GND through $1 \mathrm{k} \Omega$ resistance when EN is low OR when VL is below its UVLO threshold. |
| 25, 26 | LX1 | Step-Up Regulator Power-MOSFET n-Channel Drain and Switching Node. Connects the inductor and Schottky catch diode to both LX1 pins and minimizes the trace area for lowest EMI. |
| 27, 28 | PGND | Step-Up Regulator Power Ground |
| 29 | GD_I | Step-Up Regulator External pMOS Pass Switch Source Input. Connects to the cathode of the step-up regulator Schottky catch diode. |

# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

Pin Description (continued)

| PIN | NAME | FUNCTION |
| :---: | :---: | :---: |
| 30 | GD | Step-Up Regulator External pMOS Pass Switch Gate Input. A $10 \mu \mathrm{~A} \leq 20 \%$ current source pulls down on the gate of the external pFET when EN is high. |
| 31 | FB1 | Boost Regulator Feedback Input. Connects FB1 to the center of a resistive voltage-divider between the boost regulator output and GND to set the boost regulator output voltage. Place the resistive voltagedivider within 5 mm of FB1. |
| 32 | COMP | Compensation Pin for the Step-Up Regulator Error Amplifier. Connects a series resistor and capacitor from COMP to ground. |
| 33 | THR | VGHM Low-Level Regulation Set-Point Input. Connects THR to the center of a resistive voltage-divider between AVDD and GND to set the VGHM falling regulation level. The actual level is $10 \times$ VTHR. See the Switch Control section for details. |
| 34 | SUPP | Positive Charge-Pump Drivers Power Supply. Connects to the output of the boost regulator (AVDD) and bypasses to CPGND with a $0.1 \mu \mathrm{~F}$ capacitor. SUPP is internally connected to GD_I. |
| 35 | CPGND | Charge Pump and Buck Power Ground |
| 36 | DRVP | Positive Charge-Pump Driver Output. Connects DRVP to the positive charge-pump flying capacitor(s). |
| 37 | DLY1 | High-Voltage Switch Array Delay Input. Connects a capacitor from DLY1 to GND to set the delay time between when the positive charge pump finishes its soft-start and the startup of this high-voltage switch array. A $10 \mu \mathrm{~A}$ current source charges CDLY1. DLY1 is internally pulled to GND through $50 \Omega$ resistance when EN is low or when VL is below its UVLO threshold. |
| 38 | FBP | Positive Charge-Pump Regulator Feedback Input. Connects FBP to the center of a resistive voltagedivider between the positive charge-pump regulator output and GND to set the positive charge-pump regulator output voltage. Place the resistive voltage-divider within 5 mm of FBP. |
| 39 | VGH | Switch Input. Source of the internal high-voltage p-channel MOSFET between VGH and VGHM. |
| 40 | VGHM | Internal High-Voltage MOSFET Switch Common Terminal. VGHM is the output of the high-voltage switch-control block. |
| 41 | DRN | Switch Output. Drain of the internal high-voltage p-channel MOSFET connected to VGHM. |
| 42 | SUPN | Negative Charge-Pump Drivers Power Supply. Bypass to CPGND with a $0.1 \mu \mathrm{~F}$ capacitor. SUPN is internally connected to IN2. |
| 43 | DRVN | Negative Charge-Pump Driver Output. Connects DRVN to the negative charge-pump flying capacitor(s). |
| 45 | FBN | Negative Charge-Pump Regulator Feedback Input. Connect FBN to the center of a resistive voltagedivider between the negative output and REF to set the negative charge-pump regulator output voltage. Place the resistive voltage-divider within 5 mm of FBN. |
| 46 | REF | Reference Output. Connects a $0.22 \mu$ F capacitor from REF to GND. All power outputs are disabled until REF exceeds its UVLO threshold. |
| 47 | VREF_FB | Gamma Reference Feedback Input. Connect VREF_FB to the center of a resistive voltage-divider between VREF_O and GND to set the gamma reference output voltage. Place the resistive voltagedivider within 5 mm of VREF_FB. |
| 48 | VREF_O | Gamma Reference Output |
| - | EP | Exposed Pad. Connects EP to GND, and ties EP to a copper plane or island. Maximizes the area of this copper plane or island to improve thermal performance. |

MAX17126/MAX17126A

Figure 1. Typical Operating Circuit

# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

#### Abstract

Typical Operating Circuit The typical operating circuit (Figure 1) of the MAX17126/ MAX17126A comprise a complete power-supply system for TFT LCD TV panels. The circuit generates a +3.3 V logic supply, a +16 V source driver supply, a +35 V positive gate-driver supply, a -6V negative gate-driver supply, and $\mathrm{a} \leq 0.5 \%$ high-accuracy, high-voltage gamma reference. Table 1 lists some selected components and Table 2 lists the contact information for component suppliers.

## Detailed Description

The MAX17126/MAX17126A are multiple-output power supplies designed primarily for TFT LCD TV panels. It contains a step-down switching regulator to generate the supply for system logic, a step-up switching regulator to generate the supply for source driver, and two chargepump regulators to generate the supplies for TFT gate drivers, a high-accuracy, high-voltage reference supply for gamma correction. Each regulator features adjustable output voltage, digital soft-start, and timer-delayed fault protection. Both the step-down and step-up regulators use fixed-frequency current-mode control architecture. The two switching regulators are $180^{\circ}$ out of phase to minimize the input ripple. The internal oscillator offers two pin-selectable frequency options $(500 \mathrm{kHz} / 750 \mathrm{kHz})$, allowing users to optimize their designs based on the specific application requirements. The step-up regulator also features adjustable current limit that can be adjusted through a resistor at the CLIM pin. The MAX17126/MAX17126A include one high-performance operational amplifier designed to drive the LCD backplane (VCOM). The amplifier features high-output current ( $\leq 200 \mathrm{~mA}$ ), fast slew rate $(45 \mathrm{~V} / \mu \mathrm{s})$, wide bandwidth $(20 \mathrm{MHz})$, and rail-to-rail outputs. The high-accuracy, high-voltage gamma reference has its error controlled to within $\leq 0.5 \%$ and can deliver more than 60 mA current. In addition, the MAX17126/MAX17126A feature a highvoltage switch-control block, an internal 5V linear regulator, a 1.25 V reference output, well-defined power-up and power-down sequences, and fault and thermal-overload protection. Figure 2 shows the MAX17126/MAX17126A functional diagram.

Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs

## MAX17126/MAX17126A

Figure 2. Functional Diagram

# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

The step-Down Regulator internal n-channel MOSFET with gate driver, a lossless current-sense network, a current-limit comparator, and a PWM controller block. The external power stage consists of a Schottky diode rectifier, an inductor, and output capacitors. The output voltage is regulated by changing the duty cycle of the high-side MOSFET. A bootstrap circuit that uses a $0.1 \mu \mathrm{~F}$ flying capacitor between LX2 and BST provides the supply voltage for the high-side gate driver. Although the MAX17126/MAX17126A also include a $10 \Omega$ (typ) low-side MOSFET, this switch is used to charge the bootstrap capacitor during startup and maintains fixedfrequency operation at light load and cannot be used as a synchronous rectifier. An external Schottky diode (D2 in Figure 1) is always required.

## PWM Controller Block

The heart of the PWM control block is a multi-input, openloop comparator that sums three signals: the outputvoltage signal with respect to the reference voltage, the current-sense signal, and the slope-compensation signal. The PWM controller is a direct-summing type, lacking a traditional error amplifier and the phase shift associated with it. This direct-summing configuration approaches ideal cycle-by-cycle control over the output voltage.
The step-down controller always operates in fixed-frequency PWM mode. Each pulse from the oscillator sets the main PWM latch that turns on the high-side switch until the PWM comparator changes state. As the highside switch turns off, the low-side switch turns on. The low-side switch stays on until the beginning of the next clock cycle.

## Current Limiting and Lossless Current Sensing

The current-limit circuit turns off the high-side MOSFET switch whenever the voltage across the high-side MOSFET exceeds an internal threshold. The actual current limit is typically 3.2A for MAX17126 and 3.5A for MAX17126A.
For current-mode control, an internal lossless sense network derives a current-sense signal from the inductor DCR. The time constant of the current-sense network is not required to match the time constant of the inductor and has been chosen to provide sufficient current ramp signal for stable operation at both operating frequencies. The current-sense signal is AC-coupled into the PWM comparator, eliminating most DC output-voltage variation with load current.

Dual-Mode Feedback
The step-down regulator of the MAX17126/MAX17126A support both fixed output and adjustable output. Connect FB2 to GND to enable the 3.3V fixed-output voltage. Connect a resistive voltage-divider between OUT and GND with the center tap connected to FB2 to adjust the output voltage. Choose RB (resistance from FB2 to GND) to be between $5 \mathrm{k} \Omega$ and $50 \mathrm{k} \Omega$, and solve for RA (resistance from OUT to FB2) using the equation:

$$
R A=R B \times\left(\frac{V_{\mathrm{OUT}}}{V_{\mathrm{FB} 2}}-1\right)
$$

where $\mathrm{V}_{\mathrm{FB}}$ 2 $=1.25 \mathrm{~V}$, and VOUT may vary from 1.5 V to 5 V .
Because FB2 is a very sensitive pin, a noise filter is generally required for FB2 in adjustable-mode operation. Place an 82 pF capacitor from FB2 to GND to prevent unstable operation. No filter is required for 3.3V fixedmode operation.

Soft-Start
The step-down regulator includes a 7-bit soft-start DAC that steps its internal reference voltage from zero to 1.25 V in 128 steps. The soft-start period is 3ms (typ) and FB2 fault detection is disabled during this period. The soft-start feature effectively limits the inrush current during startup (see the Step-Down Regulator Soft-Start Waveforms in the Typical Operating Characteristics).

Step-Up Regulator
The step-up regulator employs a current-mode, fixed-frequency PWM architecture to maximize loop bandwidth and provide fast-transient response to pulsed loads typical of TFT LCD panel source drivers. The integrated MOSFET and the built-in digital soft-start function reduce the number of external components required while controlling inrush currents. The output voltage can be set from VIN to 16.5 V with an external resistive voltagedivider. The regulator controls the output voltage and the power delivered to the output by modulating duty cycle D of the internal power MOSFET in each switching cycle. The duty cycle of the MOSFET is approximated by:

$$
D \approx \frac{V_{\text {AVDD }}+V_{\text {DIODE }}-V_{I N}}{V_{\text {AVDD }}+V_{\text {DIODE }}-V_{\text {LX1 }}}
$$

where VAVDD is the output voltage of the step-up regulator, VDIODE is the voltage drop across the diode, and VLX1 is the voltage drop across the internal MOSFET.

# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

An error amplifier compares the signal at FB1 to 1.25 V and changes the COMP output. The voltage at COMP sets the peak inductor current. As the load varies, the error amplifier sources or sinks current to the COMP output accordingly to produce the inductor peak current necessary to service the load. To maintain stability at high duty cycles, a slope compensation signal is summed with the current-sense signal.
On the rising edge of the internal clock, the controller sets a flip-flop, turning on the n-channel MOSFET and applying the input voltage across the inductor. The current through the inductor ramps up linearly, storing energy in its magnetic field. Once the sum of the currentfeedback signal and the slope compensation exceed the COMP voltage, the controller resets the flip-flop and turns off the MOSFET. Since the inductor current is continuous, a transverse potential develops across the inductor that turns on diode D1. The voltage across the inductor then becomes the difference between the output voltage and the input voltage. This discharge condition forces the current through the inductor to ramp back down, transferring the energy stored in the magnetic field to the output capacitor and the load. The MOSFET remains off for the rest of the clock cycle.

## Step-Up Regulator External pMOS Pass Switch

As shown in Figure 1, a series external p-channel MOSFET can be installed between the cathode of the step-up regulator Schottky catch diode and the VAVDD filter capacitors. This feature is used to sequence power to AVDD after the MAX17126/MAX17126A have proceeded through normal startup to limit input surge current
during the output capacitor initial charge, and to provide true shutdown when the step-up regulator is disabled. When EN is low, GD is internally pulled up to the GD_I through a $25 \Omega$ resistor. Once EN is high and the negative charge-pump regulator is in regulation, the GD starts pulling down with a $10 \mu \mathrm{~A}$ (typ) internal current source. The external p-channel MOSFET turns on and connects the cathode of the step-up regulator Schottky catch diode to the step-up regulator load capacitors when GD falls below the turn-on threshold of the MOSFET. When VGD reaches VGD I-6V(GD done), the step-up regulator is enabled and initiates a soft-start routine.
When not using this feature, leave GD high impedance, and connect GD_I to the output of the step-up converter.

## Soft-Start

The step-up regulator achieves soft-start by linearly ramping up its internal current limit. The soft-start is either done internally when the capacitance on pin SS is $<200 \mathrm{pF}$ or externally when capacitance on pin SS is > 200pF. The internal soft-start ramps up the current limit in 128 steps in 12 ms . The external soft-start terminates when the SS pin voltage reaches 1.25 V . The soft-start feature effectively limits the inrush current during startup (see the Step-Up Regulator Soft-Start Waveforms in the Typical Operating Characteristics).

## Positive Charge-Pump Regulator

The positive charge-pump regulator (Figure 3) is typically used to generate the positive supply rail for the TFT LCD gate driver ICs. The output voltage is set with an external resistive voltage-divider from its output to GND with the midpoint connected to FBP. The number of charge-pump stages and the setting of the feedback divider determine

Figure 3. Positive Charge-Pump Regulator Block Diagram

## Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs

the output voltage of the positive charge-pump regulator. The charge pump includes a high-side p-channel MOSFET (P1) and a low-side n-channel MOSFET (N1) to control the power transfer as shown in Figure 3.
During the first half cycle, N1 turns on and charges flying capacitors C12 and C13 (Figure 3). During the second half cycle, N1 turns off and P1 turns on, level shifting C12 and C13 by VSUPP volts. If the voltage across C15 (VGH) plus a diode drop (VD) is smaller than the level-shifted flying-capacitor voltage (VC13) plus VSUPP, charge flows from C13 to C15 until the diode (D3) turns off. The amount of charge transferred to the output is determined by the error amplifier that controls N 1 's on-resistance.
Each time it is enabled, the positive charge-pump regulator goes through a soft-start routine by ramping up its internal reference voltage from 0 to 1.25 V in 128 steps. The soft-start period is 2 ms (typ) and FBP fault detection is disabled during this period. The soft-start feature effectively limits the inrush current during startup.

## Negative Charge-Pump Regulator

The negative charge-pump regulator is typically used to generate the negative supply rail for the TFT LCD gate driver ICs. The output voltage is set with an external resistive voltage-divider from its output to REF with the midpoint connected to FBN. The number of charge-pump stages and the setting of the feedback divider determine the output of the negative charge-pump regulator. The charge-pump controller includes a high-side p-channel MOSFET (P2) and a low-side n-channel MOSFET (N2) to control the power transfer as shown in Figure 4.
During the first half cycle, P2 turns on, and flying capacitor C10 charges to VSUPN minus a diode drop (Figure 4). During the second half cycle, P2 turns off, and N2 turns on, level shifting C10. This connects C10 in parallel with reservoir capacitor C11. If the voltage across C11 minus a diode drop is greater than the voltage across C10, charge flows from C11 to C10 until the diode (D4) turns off. The amount of charge transferred from the output is determined by the error amplifier that controls N2's onresistance.

Figure 4. Negative Charge-Pump Regulator Block Diagram

# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

Figure 5. Switch Control

The negative charge-pump regulator is enabled after the step-down regulator finishes soft-start. Each time it is enabled, the negative charge-pump regulator goes through a soft-start routine by ramping down its internal reference voltage from 1.25 V to 250 mV in 128 steps. The soft-start period is 1.8 ms (typ) and FBN fault detection is disabled during this period. The soft-start feature effectively limits the inrush current during startup.

## High-Voltage Switch Control

The MAX17126/MAX17126As' high-voltage switch control block (Figure 5) consists of two high-voltage p-channel MOSFETs: Q1, between VGH, and VGHM and Q2, between VGHM and DRN. The switch control block is enabled when VDLY1 exceeds VREF. Q1 and Q2 are controlled by GVOFF.
When GVOFF is logic-high, Q1 turns on and Q2 turns off, connecting VGHM to VGH. When GVOFF is logiclow, Q1 turns off and Q2 turns on, connecting VGHM to DRN. VGHM can then be discharged through a resistor connected between DRN and GND or AVDD. Q2 turns off and stops discharging VGHM when VGHM reaches 10 times the voltage on THR.

The switch control block is disabled and DLY1 is held low when the LCD is shut down or in a fault state.

## Operational Amplifier

The operational amplifier is typically used to drive the LCD backplane (VCOM). It features $\pm 200 \mathrm{~mA}$ output short-circuit current, $45 \mathrm{~V} / \mu \mathrm{s}$ slew rate, and $20 \mathrm{MHz} / 3 \mathrm{~dB}$ bandwidth. The rail-to-rail input and output capability maximizes system flexibility.

## Short-Circuit Current Limit and Input Clamp

 The operational amplifier limits short-circuit current to approximately $\pm 200 \mathrm{~mA}$ if the output is directly shorted to VOP or to OGND. If the short-circuit condition persists, the junction temperature of the IC rises until it reaches the thermal-shutdown threshold $\left(+160^{\circ} \mathrm{C}\right.$ typ). Once the junction temperature reaches the thermal-shutdown threshold, an internal thermal sensor immediately sets the thermal fault latch, shutting off all the IC's outputs. The device remains inactive until the input voltage is cycled. The operational amplifiers have 4V input clamp structures in series with a $500 \Omega$ resistance and a diode (Figure 6).
# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

Figure 6. Op Amp Input Clamp Structure
Driving Pure Capacitive Load
The LCD backplane consists of a distributed series capacitance and resistance, a load that can be easily driven by the operational amplifier. However, if the operational amplifier is used in an application with a pure capacitive load, steps must be taken to ensure stable operation. As the operational amplifier's capacitive load increases, the amplifier's bandwidth decreases and gain peaking increases. A $5 \Omega$ to $50 \Omega$ small resistor placed between OPO and the capacitive load reduces peaking, but also reduces the gain. An alternative method of reducing peaking is to place a series RC network (snubber) in parallel with the capacitive load. The RC network does not continuously load the output or reduce the gain. Typical values of the resistor are between $100 \Omega$ and $200 \Omega$, and the typical value of the capacitor is 10 nF .

## Linear Regulator (VL)

The MAX17126/MAX17126A include an internal linear regulator. INVL is the input of the linear regulator. The input voltage range is between 8 V and 16.5 V . The output voltage is set to 5 V . The regulator powers the internal MOSFET drivers, PWM controllers, charge-pump regulators, and logic circuitry. The total external load capability is 25 mA . Bypass VL to GND with a minimum $1 \mu \mathrm{~F}$ ceramic capacitor.

Reference Voltage (REF)
The reference output is nominally 1.25 V , and can source at least $50 \mu \mathrm{~A}$ (see Typical Operating Characteristics). VL is the input of the internal reference block. Bypass REF with a $0.22 \mu \mathrm{~F}$ ceramic capacitor connected between REF and GND.

## High-Accuracy, <br> High-Voltage Gamma Reference

The LDO is typically used to drive gamma-correction divider string. Its output voltage is adjustable through a resistor-divider. This LDO features high output accuracy ( $\pm 0.5 \%$ ) and low-dropout voltage ( 0.25 V typ) and can supply at least 60 mA .

PGOOD Function PGOOD is an open-drain output that connects to GND when VDET is below its detection threshold ( 1.25 V typ). PGOOD is active after VL rises above UVLO threshold.

## Frequency Selection and Out-of-Phase Operation (FSEL)

 The step-down regulator and step-up regulator use the same internal oscillator. The FSEL input selects the switching frequency. Table 3 shows the switching frequency based on the FSEL connection. High-frequency $(750 \mathrm{kHz})$ operation optimizes the application for the smallest component size, trading off efficiency due to higher switching losses. Low-frequency ( 500 kHz ) operation offers the best overall efficiency at the expense of component size and board space.To reduce the input RMS current, the step-down regulator and the step-up regulator operate $180^{\circ}$ out of phase from each other. The feature allows the use of less input capacitance.

Table 3. Frequency Selection

| FSEL | SWITCHING FREQUENCY <br> $(\mathbf{k H z})$ |
| :---: | :---: |
| $\mathrm{VL}, \mathrm{INVL}, \mathrm{OR} \mathrm{FLOAT}$ | 750 |
| GND | 500 |

## Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs

## Power-Up Sequence

The step-down regulator starts up when the MAX17126/ MAX17126As' internal reference voltage (REF) is above its undervoltage lockout (UVLO) threshold. Once the step-down regulator soft-start is done, the FB2 faultdetection circuit and the negative charge pump are enabled. Negative charge-pump fault protection is enabled after its own soft-start is done.
When EN goes to logic-high, a $10 \mu \mathrm{~A}$ current source starts to pull down on GD, turning on the external GD_IAVDD PMOS switch. When VGD reaches GD-done threshold (VGD_I - 6V), the step-up regulator is enabled. Gamma reference is enabled at the same time.

The MAX17126/MAX17126A simplify system design by including an internal 12 ms soft-start for the step-up regulator. When the capacitor on the SS pin is less than 200 pF , the internal 12 ms soft-start is in place. This saves one capacitor from system design. If an external capacitor greater than 200 pF is used, a $5 \mu \mathrm{~A}$ current source charges the SS capacitor pin and when the SS voltage reaches 1.25 V , soft-start is done. The FB1 fault-detection circuit is enabled after this soft-start is done.
The positive charge pump is also enabled after the step-up regulator finishes its soft-start. After the positive charge pump's soft-start is done, the FBP fault-detection circuit is enabled, as well as the high-voltage switch delay block. CDLY1 is charged with an internal $10 \mu \mathrm{~A}$ current source and VDLY1 rises linearly. When VDLY1 reaches REF, the high-voltage switch block is enabled.

Figure 7. Power-Up Sequence

# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

The step-down regulator, step-up regulator, positive charge pump, negative charge pump, and high-voltage switching block all start to shut down when INVL drops below its UVLO threshold. VL stays flat until INVL does not have enough headroom. Reference REF starts to fall after VL drops below its UVLO threshold.
Gamma reference GREF stays flat until AVDD does not have enough headroom. A pMOS switch turns on after VL drops below its UVLO threshold to guarantee GREF does not go over AVDD.
PGOOD is pulled low after its input voltage (buck output in this case) drops below the designed threshold. After VL drops below its UVLO threshold, PGOOD gives up control and is resistively pulled up to its input voltage.
The high-voltage switching block output VGHM falls until VL drops below its UVLO threshold, after which it is in high impedance.

Figure 8. Power-Down Sequence

Fault Protection
During steady-state operation, if any output of the four regulators' output (step-down regulator, step-up regulator, positive charge-pump regulator, and negative charge-pump regulator) goes lower than its respective fault-detection threshold, the MAX17126 activates an internal fault timer. If any condition or the combination of conditions indicates a continuous fault for the fault timer duration ( 50 ms typ), the MAX17126A latches off all its outputs while the MAX17126 latches off all the outputs except the buck regulator (latched off only when the fault happens on its output).
If a short has happened to any of the four regulator outputs, no fault timer is applied; the part latches off immediately. Pay special attention to shorts on the stepup regulator and positive charge pump. Make sure when a short happens, negative ringing on VREF_I (connected to step-up regulator output) and VGH (connected to positive charge-pump output) does not exceed Absolute Maximum Ratings. Otherwise, physical damage of the part may occur. Cycle the input voltage to clear the fault latch and restart the supplies.

Thermal-Overload Protection
The thermal-overload protection prevents excessive power dissipation from overheating the MAX17126/ MAX17126A. When the junction temperature exceeds $\mathrm{TJ}=+160^{\circ} \mathrm{C}$, a thermal sensor immediately activates the fault protection that shuts down all the outputs. Cycle the input voltage to clear the fault latch and restart the MAX17126/MAX17126A.
The thermal-overload protection protects the controller in the event of fault conditions. For continuous operation, do not exceed the absolute maximum junction temperature rating of $\mathrm{T} J=+150^{\circ} \mathrm{C}$.

## Design Procedure

## Step-Down Regulator

 Inductor SelectionThree key inductor parameters must be specified: inductance value (L), peak current (IPEAK), and DC resistance (RDC). The following equation includes a constant, LIR, which is the ratio of peak-to-peak inductor ripple current to DC load current. A higher LIR value allows smaller inductance, but results in higher losses and higher ripple. A good compromise between size and losses is typically found at a $30 \%$ ripple current-toload current ratio $(L I R=0.3)$ that corresponds to a peak inductor current 1.15 times the DC load current:

$$
L_{2}=\frac{V_{\mathrm{OUT}} \times\left(\mathrm{V}_{\text {IN2 }}-\mathrm{V}_{\mathrm{OUT}}\right)}{\mathrm{V}_{\text {IN2 }} \times \mathrm{f}_{\mathrm{SW}} \times \mathrm{I}_{\mathrm{OUT}(\mathrm{MAX})} \times \mathrm{LIR}}
$$

# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

where $\operatorname{IOUT}(\mathrm{MAX})$ is the maximum DC load current, and the switching frequency fSW is 750 kHz when FSEL is tied to $\mathrm{VL}, 500 \mathrm{kHz}$ when FSEL is tied to GND. The exact inductor value is not critical and can be adjusted to make trade-offs among size, cost, and efficiency. Lower inductor values minimize size and cost, but they also increase the output ripple and reduce the efficiency due to higher peak currents. On the other hand, higher inductor values increase efficiency, but at some point resistive losses due to extra turns of wire exceed the benefit gained from lower AC current levels.
The inductor's saturation current must exceed the peak inductor current. The peak current can be calculated by:

$$
\begin{aligned}
& \text { IOUT_RIPPLE }=\frac{V_{\text {OUT }} \times\left(V_{\text {IN2 }}-V_{\text {OUT }}\right)}{f_{S W} \times L_{2} \times V_{\text {IN2 }}} \\
& \text { IOUT_PEAK }=\text { IOUT }^{\text {OMAX })}+\frac{\text { I OUT_RIPPLE }^{2}}{2}
\end{aligned}
$$

The inductor's DC resistance should be low for good efficiency. Find a low-loss inductor having the lowest possible DC resistance that fits in the allotted dimensions. Ferrite cores are often the best choice. Shieldedcore geometries help keep noise, EMI, and switching waveform jitter low.
Considering the typical operation circuit in Figure 1, the maximum load current IOUT(MAX) is 1.5 A with a 3.3 V output and a typical 12 V input voltage. Choosing an LIR of 0.4 at this operation point:

$$
\mathrm{L}_{2}=\frac{3.3 \mathrm{~V} \times(12 \mathrm{~V}-3.3 \mathrm{~V})}{12 \mathrm{~V} \times 750 \mathrm{kHz} \times 1.5 \mathrm{~A} \times 0.4} \approx 5.3 \mu \mathrm{H}
$$

Pick $L_{2}=4.7 \mu \mathrm{H}$. At that operation point, the ripple current and the peak current are:

$$
\begin{gathered}
\text { IOUT_RIPPLE }=\frac{3.3 \mathrm{~V} \times(12 \mathrm{~V}-3.3 \mathrm{~V})}{750 \mathrm{kHz} \times 4.7 \mathrm{H} \times 12 \mathrm{~V}}=0.68 \mathrm{~A} \\
\text { IOUT_PEAK }=1.5 \mathrm{~A}+\frac{0.68 \mathrm{~A}}{2}=1.84 \mathrm{~A}
\end{gathered}
$$

## Input Capacitors

The input filter capacitors reduce peak currents drawn from the power source and reduce noise and voltage ripple on the input caused by the regulator's switching. They are usually selected according to input ripple current requirements and voltage rating, rather than capacitance value. The input voltage and load current determine the RMS input ripple current (IRMS):

$$
\mathrm{I}_{\mathrm{RMS}}=\mathrm{I}_{\mathrm{OUT}} \times \frac{\sqrt{\mathrm{V}_{\mathrm{OUT}} \times\left(\mathrm{V}_{\mathrm{IN} 2}-\mathrm{V}_{\mathrm{OUT}}\right)}}{\mathrm{V}_{\mathrm{IN} 2}}
$$

The worst case is IRMS $=0.5 \times$ IOUT that occurs at VIN2 $=2 \times$ VOUT.
For most applications, ceramic capacitors are used because of their high ripple current and surge current capabilities. For optimal circuit long-term reliability, choose an input capacitor that exhibits less than $+10^{\circ} \mathrm{C}$ temperature rise at the RMS input current corresponding to the maximum load current.

## Output Capacitor Selection

Since the MAX17126/MAX17126As' step-down regulator is internally compensated, it is stable with any reasonable amount of output capacitance. However, the actual capacitance and equivalent series resistance (ESR) affect the regulator's output ripple voltage and transient response. The rest of this section deals with how to determine the output capacitance and ESR needs according to the ripple voltage and load-transient requirements.
The output voltage ripple has two components: variations in the charge stored in the output capacitor, and the voltage drop across the capacitor's ESR caused by the current into and out of the capacitor:

$$
\begin{aligned}
& \text { VOUT_RIPPLE }=\text { V }_{\text {OUT_RIPPLE(ESR) }}+\mathrm{V}_{\text {OUT_RIPPLE(C) }} \\
& V_{\text {OUT_RIPPLE(ESR) }}=\text { I OUT_RIPPLE } \times \mathrm{R}_{\text {ESR_OUT }}
\end{aligned}
$$

$$
\mathrm{V}_{\text {OUT_RIPPLE }}(\mathrm{C})=\frac{\mathrm{l}_{\text {OUT_RIPPLE }}}{8 \times \mathrm{C}_{\text {OUT }} \times \mathrm{f}_{\mathrm{SW}}}
$$

where IOUT_RIPPLE is defined in the Step-Down Regulator Inductor Selection section, COUT (C5 in Figure 1) is the output capacitance, and RESR_OUT is the ESR of the output capacitor COUT. In Figure 1's circuit, the inductor ripple current is 0.68 A . If the voltage-ripple requirement of Figure 1 's circuit is $\leq 1 \%$ of the 3.3 V output, then the total peak-to-peak ripple voltage should be less than 66 mV . Assuming that the ESR ripple and the capacitive ripple each should be less than $50 \%$ of the total peak-to-peak ripple, then the ESR should be less than $48.5 \mathrm{~m} \Omega$ and the output capacitance should be more than $3.4 \mu \mathrm{~F}$ to meet the total ripple requirement. A $22 \mu \mathrm{~F}$ capacitor with ESR (including PCB trace resistance) of $10 \mathrm{~m} \Omega$ is selected for the typical operating circuit in Figure 1, which easily meets the voltage ripple requirement.

## Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs

The step-down regulator's output capacitor and ESR also affect the voltage undershoot and overshoot when the load steps up and down abruptly. The undershoot and overshoot also have two components: the voltage steps caused by ESR, and voltage sag and soar due to the finite capacitance and inductor slew rate. Use the following formulas to check if the ESR is low enough and the output capacitance is large enough to prevent excessive soar and sag.
The amplitude of the ESR step is a function of the load step and the ESR of the output capacitor:

$$
V_{\text {OUT_ESR_STEP }}=\Delta \mathrm{l}_{\text {OUT }} \times \mathrm{R}_{\text {ESR_OUT }}
$$

The amplitude of the capacitive sag is a function of the load step, the output capacitor value, the inductor value, the input-to-output voltage differential, and the maximum duty cycle:

$$
\mathrm{V}_{\text {OUT_SAG }}=\frac{\mathrm{L}_{2} \times\left(\Delta \mathrm{I}_{\mathrm{OUT}}\right)^{2}}{2 \times \mathrm{C}_{\mathrm{OUT}} \times\left(\mathrm{V}_{\mathrm{IN2}(\mathrm{MIN})} \times \mathrm{D}_{\mathrm{MAX}}-\mathrm{V}_{\mathrm{OUT}}\right)}
$$

The amplitude of the capacitive soar is a function of the load step, the output capacitor value, the inductor value, and the output voltage:

$$
\mathrm{V}_{\text {OUT_SOAR }}=\frac{\mathrm{L}_{2} \times\left(\Delta \mathrm{l}_{\mathrm{OUT}}\right)^{2}}{2 \times \mathrm{C}_{\mathrm{OUT}} \times \mathrm{V}_{\mathrm{OUT}}}
$$

Keeping the full-load overshoot and undershoot less than $3 \%$ ensures that the step-down regulator's natural integrator response dominates. Given the component values in the circuit of Figure 1, during a full 1.5A step load transient, the voltage step due to capacitor ESR is negligible. The voltage sag and soar are 76 mV and 73 mV , respectively.

## Rectifier Diode

The MAX17126/MAX17126As' high switching frequency demands a high-speed rectifier. Schottky diodes are recommended for most applications because of their fast recovery time and low forward voltage. In general, a 2A Schottky diode works well in the MAX17126/MAX17126A's step-up regulator.

## Step-Up Regulator

Inductor Selection
The inductance value, peak current rating, and series resistance are factors to consider when selecting the inductor. These factors influence the converter's efficiency, maximum output load capability, transient response time, and output voltage ripple. Physical size and cost are also important factors to be considered.

The maximum output current, input voltage, output voltage, and switching frequency determine the inductor value. Very high inductance values minimize the current ripple, and therefore, reduce the peak current, which decreases core losses in the inductor and I2R losses in the entire power path. However, large inductor values also require more energy storage and more turns of wire that increase physical size and can increase I2R losses in the inductor. Low inductance values decrease the physical size, but increase the current ripple and peak current. Finding the best inductor involves choosing the best compromise between circuit efficiency, inductor size, and cost.
The equations used here include a constant LIR, which is the ratio of the inductor peak-to-peak ripple current to the average DC inductor current at the full-load current. The best trade-off between inductor size and circuit efficiency for step-up regulators generally has an LIR between 0.3 and 0.5 . However, depending on the AC characteristics of the inductor core material and ratio of inductor resistance to other power-path resistances, the best LIR can shift up or down. If the inductor resistance is relatively high, more ripple can be accepted to reduce the number of turns required and increase the wire diameter. If the inductor resistance is relatively low, increasing inductance to lower the peak current can decrease losses throughout the power path. If extremely thin high-resistance inductors are used, as is common for LCD panel applications, the best LIR can increase to between 0.5 and 1.0.
Once a physical inductor is chosen, higher and lower values of the inductor should be evaluated for efficiency improvements in typical operating regions.
Calculate the approximate inductor value using the typical input voltage (VIN), the maximum output current (IAVDD(MAX)), the expected efficiency ( $\eta$ TYP) taken from an appropriate curve in the Typical Operating Characteristics, and an estimate of LIR based on the above discussion:

$$
L_{1}=\left(\frac{V_{I N}}{V_{\text {AVDD }}}\right)^{2}\left(\frac{V_{A V D D}-V_{I N}}{I_{\text {AVDD(MAX }} \times f_{S W}}\right)\left(\frac{\eta_{\text {TYP }}}{L I R}\right)
$$

Choose an available inductor value from an appropriate inductor family. Calculate the maximum DC input current at the minimum input voltage $\mathrm{VIN}(\mathrm{MIN})$ using conservation of energy and the expected efficiency at that operating point ( $\mathrm{\eta MIN}$ ) taken from an appropriate curve in the Typical Operating Characteristics:

$$
\mathrm{I}_{\mathrm{IN}(\mathrm{DC}, \mathrm{MAX})}=\frac{\mathrm{I}_{\mathrm{AVDD}(\mathrm{MAX})} \times \mathrm{V}_{\mathrm{AVDD}}}{\mathrm{~V}_{\mathrm{IN}(\mathrm{MIN})} \times \eta_{\mathrm{MIN}}}
$$

## Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs

Calculate the ripple current at that operating point and the peak current required for the inductor:

$$
\begin{aligned}
& I_{\text {AVDD_RIPPLE }}=\frac{\mathrm{V}_{\text {IN(MIN })} \times\left(\mathrm{V}_{\text {AVDD }}-\mathrm{V}_{\text {IN(MIN })}\right)}{\mathrm{L}_{\text {AVDD }} \times \mathrm{V}_{\text {AVDD }} \times f_{\mathrm{SW}}} \\
& \mathrm{I}_{\text {AVDD_PEAK }}=I_{\text {IN(DC,MAX })}+\frac{\mathrm{I}_{\text {AVDD_RIPPLE }}}{2}
\end{aligned}
$$

The inductor's saturation current rating and the MAX17126/ MAX17126As' LX1 current limit should exceed IAVDD_ PEAK and the inductor's DC current rating should exceed IIN(DC,MAX). For good efficiency, choose an inductor with less than $0.1 \Omega$ series resistance.
Considering the typical operating circuit (Figure 1), the maximum load current (IAVDD(MAX)) is 1 A with a 16 V output and a typical input voltage of 12 V . Choosing an LIR of 0.3 and estimating efficiency of $90 \%$ at this operating point:

$$
\mathrm{L}_{1}=\left(\frac{12 \mathrm{~V}}{16 \mathrm{~V}}\right)^{2}\left(\frac{16 \mathrm{~V}-12 \mathrm{~V}}{1 \mathrm{~A} \times 750 \mathrm{kHz}}\right)\left(\frac{90 \%}{0.3}\right)=9 \mu \mathrm{H}
$$

Using the circuit's minimum input voltage ( 8 V ) and estimating efficiency of $85 \%$ at that operating point:

$$
I_{\text {IN }(D C, M A X)}=\frac{1 \mathrm{~A} \times 16 \mathrm{~V}}{8 \mathrm{~V} \times 85 \%} \approx 2.35 \mathrm{~A}
$$

The ripple current and the peak current are:

$$
\begin{gathered}
\text { I AVDD_RIPPLE }=\frac{8 \mathrm{~V} \times(16 \mathrm{~V}-8 \mathrm{~V})}{10 \mu \mathrm{H} \times 16 \mathrm{~V} \times 750 \mathrm{kHz}} \approx 0.53 \mathrm{~A} \\
\text { I }_{\text {AVDD_PEAK }}=2.35 \mathrm{~A}+\frac{0.53 \mathrm{~A}}{2} \approx 2.62 \mathrm{~A}
\end{gathered}
$$

## Output Capacitor Selection

The total output voltage ripple has two components: the capacitive ripple caused by the charging and discharging of the output capacitance, and the ohmic ripple due to the capacitor's equivalent series resistance (ESR):

$$
\begin{gathered}
V_{\text {AVDD_RIPPLE }}=V_{\text {AVDD_RIPPLE(C) }}+V_{\text {AVDD_RIPPLE(ESR) }} \\
V_{\text {AVDD_RIPPLE(C) }} \approx \frac{I_{\text {AVDD }}}{\mathrm{C}_{\text {AVDD }}}\left(\frac{V_{\text {AVDD }}-V_{\text {IN }}}{V_{\text {AVDD }}{ }^{\dagger} S}\right)
\end{gathered}
$$

and:

$$
\left.\mathrm{V}_{\text {AVDD_RIPPLE(ESR) }} \approx\right|_{\text {AVDD_PEAK }} R_{\text {ESR_AVDD }}
$$

where IAVDD_PEAK is the peak inductor current (see the Inductor Selection section). For ceramic capacitors,
the output voltage ripple is typically dominated by VAVDD_RIPPLE(C). The voltage rating and temperature characteristics of the output capacitor must also be considered. Note that all ceramic capacitors typically have large temperature coefficient and bias voltage coefficients. The actual capacitor value in circuit is typically significantly less than the stated value.

## Input Capacitor Selection

The input capacitor reduces the current peaks drawn from the input supply and reduces noise injection into the IC. A $22 \mu \mathrm{~F}$ ceramic capacitor is used in the typical operating circuit (Figure 1) because of the high source impedance seen in typical lab setups. Actual applications usually have much lower source impedance since the step-up regulator often runs directly from the output of another regulated supply. Typically, the input capacitance can be reduced below the values used in the typical operating circuit.

Rectifier Diode
The MAX17126/MAX17126As' high switching frequency demands a high-speed rectifier. Schottky diodes are recommended for most applications because of their fast recovery time and low forward voltage. In general, a 2A Schottky diode complements the internal MOSFET well.

## Output Voltage Selection

The output voltage of the step-up regulator can be adjusted by connecting a resistive voltage-divider from the output (VAVDD) to GND with the center tap connected to FB1 (see Figure 1). Select R2 in the $10 \mathrm{k} \Omega$ to $50 \mathrm{k} \Omega$ range. Calculate R1 with the following equation:

$$
R 1=R 2 \times\left(\frac{V_{\mathrm{AVDD}}}{V_{\mathrm{FB} 1}}-1\right)
$$

where $\mathrm{V}_{\text {FB1 }}$, the step-up regulator's feedback set point, is 1.25 V . Place R1 and R2 close to the IC.

## Loop Compensation

Choose RCOMP to set the high-frequency integrator gain for fast-transient response. Choose Ccomp to set the integrator zero to maintain loop stability.
For low-ESR output capacitors, use the following equations to obtain stable performance and good transient response:

$$
\begin{aligned}
& \mathrm{R}_{\mathrm{COMP}} \approx \frac{100 \times \mathrm{V}_{\text {IN }} \times \mathrm{V}_{\mathrm{AVDD}} \times \mathrm{C}_{\mathrm{AVDD}}}{\mathrm{~L}_{\mathrm{AVDD}} \times I_{\mathrm{AVDD}(\mathrm{MAX})}} \\
& \mathrm{C}_{\mathrm{COMP}} \approx \frac{\mathrm{~V}_{\mathrm{AVDD}} \times \mathrm{C}_{\mathrm{AVDD}}}{10 \times I_{\mathrm{AVDD}(\mathrm{MAX})} \times \mathrm{R}_{\mathrm{COMP}}}
\end{aligned}
$$

# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

To further optimize transient response, vary RCOMP in $20 \%$ steps and Ccomp in $50 \%$ steps while observing transient response waveforms.

## Charge-Pump Regulators

Selecting the Number of Charge-Pump Stages
For highest efficiency, always choose the lowest number of charge-pump stages that meet the output requirement. The number of positive charge-pump stages is given by:

$$
n_{\mathrm{POS}}=\frac{\mathrm{V}_{\mathrm{GH}}+\mathrm{V}_{\mathrm{DROPOUT}}-V_{\mathrm{AVDD}}}{V_{\mathrm{SUPP}}-2 \times \mathrm{V}_{\mathrm{D}}}
$$

where nPOS is the number of positive charge-pump stages, $V_{G H}$ is the output of the positive charge-pump regulator, VSUPP is the supply voltage of the chargepump regulators, $\mathrm{VD}_{\mathrm{D}}$ is the forward voltage drop of the charge-pump diode, and VDROPOUT is the dropout margin for the regulator. Use VDROPOUT $=300 \mathrm{mV}$.
The number of negative charge-pump stages is given by:

$$
n_{\mathrm{NEG}}=\frac{-\mathrm{V}_{\mathrm{GOFF}}+\mathrm{V}_{\mathrm{DROPOUT}}}{\mathrm{~V}_{\mathrm{SUPN}}-2 \times \mathrm{V}_{\mathrm{D}}}
$$

where nNEG is the number of negative charge-pump stages and VGOFF is the output of the negative chargepump regulator.
The above equations are derived based on the assumption that the first stage of the positive charge pump is connected to VAVDD and the first stage of the negative charge pump is connected to ground. Sometimes fractional stages are more desirable for better efficiency. This can be done by connecting the first stage to VOUT or another available supply. If the first charge-pump stage is powered from VoUT, then the above equations become:

$$
\begin{gathered}
n_{\text {POS }}=\frac{V_{G H}+V_{\text {DROPOUT }}-V_{\text {OUT }}}{V_{\text {SUPP }}-2 \times V_{D}} \\
n_{\text {NEG }}=\frac{-V_{\text {GOFF }}+V_{\text {DROPOUT }}+V_{\text {OUT }}}{V_{\text {SUPN }}-2 \times V_{D}}
\end{gathered}
$$

Flying Capacitors
Increasing the flying capacitor CX (connected to DRVP and DRVN) value lowers the effective source impedance and increases the output current capability. Increasing the capacitance indefinitely has a negligible effect on output current capability because the internal switch resistance and the diode impedance place a lower limit
on the source impedance. A $0.1 \mu \mathrm{~F}$ ceramic capacitor works well in most low-current applications. The flying capacitor's voltage rating must exceed the following:

$$
\mathrm{V}_{\mathrm{CX}}>\mathrm{n}_{\mathrm{POS}(\mathrm{NEG})} \times \mathrm{V}_{\mathrm{SUPP}(\mathrm{SUPN})}
$$

where $\mathrm{nPOS}(\mathrm{NEG})$ is the number of stages in which the flying capacitor appears. It is the same as the number of charge-pump stages.

Charge-Pump Output Capacitor Increasing the output capacitance or decreasing the ESR reduces the output ripple voltage and the peak-to-peak transient voltage. With ceramic capacitors, the output voltage ripple is dominated by the capacitance value. Use the following equation to approximate the required capacitor value:

$$
\mathrm{C}_{\mathrm{OUT}} \mathrm{CP} \geq \frac{\mathrm{l}_{\text {LOAD_CP }}}{2 \times \mathrm{f}_{S W} \times \mathrm{V}_{\text {RIPPLE_CP }}}
$$

where COUT_CP is the output capacitor of the charge pump, ILOAD_CP is the load current of the charge pump, and VRIPPLE_CP is the peak-to-peak value of the output ripple.

## Output Voltage Selection

Adjust the positive charge-pump regulator's output voltage by connecting a resistive voltage-divider from VGH output to GND with the center tap connected to FBP (Figure 1). Select the lower resistor of divider R4 in the $10 \mathrm{k} \Omega$ to $30 \mathrm{k} \Omega$ range. Calculate upper resistor R3 with the following equation:

$$
\mathrm{R} 3=\mathrm{R} 4 \times\left(\frac{\mathrm{V}_{\mathrm{VGH}}}{\mathrm{~V}_{\mathrm{FBP}}}-1\right)
$$

where $V_{F B P}=1.25 \mathrm{~V}$ (typ).
Adjust the negative charge-pump regulator's output voltage by connecting a resistive voltage-divider from VGOFF to REF with the center tap connected to FBN (Figure 1). Select R6 in the $20 \mathrm{k} \Omega$ to $68 \mathrm{k} \Omega$ range. Calculate R5 with the following equation:

$$
R 5=R 6 \times \frac{V_{F B N}-V_{G O F F}}{V_{R E F}-V_{F B N}}
$$

where $V_{\text {FBN }}=250 \mathrm{mV}$, $\mathrm{V}_{\text {REF }}=1.25 \mathrm{~V}$. Note that REF can only source up to $50 \mu \mathrm{~A}$, using a resistor less than $20 \mathrm{k} \Omega$, for R6 results in a higher bias current than REF can supply.

# Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs 

## High-Accuracy, High-Voltage Gamma Reference Output-Voltage Selection

The output voltage of the high-accuracy LDO is set by connecting a resistive voltage-divider from the output (VREF_O) to AGND with the center tap connected to VREF_FB (see Figure 1). Select R10 in the $10 \mathrm{k} \Omega$ to $50 \mathrm{k} \Omega$ range. Calculate R9 with the following equation:

$$
R 9=R 10 \times\left(\frac{V_{\text {REF_O }}}{V_{\text {REF_FB }}}-1\right)
$$

where VREF_FB, the LDO's feedback set point, is 1.25 V . Place R9 and R10 close to the IC.

Input and Output Capacitor Selection To ensure stability of the LDO, use a minimum of $1 \mu \mathrm{~F}$ on the regulator's input (VREF_I) and a minimum of $2.2 \mu \mathrm{~F}$ on the regulator's output (VREF_O). Place the capacitors near the pins and connect their ground connections directly together.

## Set the PGOOD Threshold Voltage

PGOOD threshold voltage can be adjusted by connecting a resistive voltage-divider from input VIN to GND with the center tap connected to VDET (see Figure 1). Select R8 in the $10 \mathrm{k} \Omega$ to $50 \mathrm{k} \Omega$ range. Calculate R7 with the following equation:

$$
R 7=R 8 \times\left(\frac{V_{\text {IN_PGOOD }}}{V_{\text {DET }}}-1\right)
$$

where V DET $=1.25 \mathrm{~V}$ is the V DET threshold set point. VIN_PGOOD is the desired PGOOD threshold voltage. Place R7 and R8 close to the IC.

## PCB Layout and Grounding

Careful PCB layout is important for proper operation. Use the following guidelines for good PCB layout:

- Minimize the area of respective high-current loops by placing each DC/DC converter's inductor, diode, and output capacitors near its input capacitors and its LX_ and PGND pins. For the step-down regulator, the high-current input loop goes from the positive terminal of the input capacitor to the IC's IN2 pin, out of LX2, to the inductor, to the positive terminals of the output capacitors, reconnecting the output capacitor and input capacitor ground terminals. The highcurrent output loop is from the inductor to the positive terminals of the output capacitors, to the negative terminals of the output capacitors, and to the Schottky diode (D2). For the step-up regulator, the high-current
input loop goes from the positive terminal of the input capacitor to the inductor, to the IC's LX1 pin, out of PGND, and to the input capacitor's negative terminal. The high-current output loop is from the positive terminal of the input capacitor to the inductor, to the output diode (D1), to the positive terminal of the output capacitors, reconnecting between the output capacitor and input capacitor ground terminals. Connect these loop components with short, wide connections. Avoid using vias in the high-current paths. If vias are unavoidable, use many vias in parallel to reduce resistance and inductance.
- Create a power ground island for the step-down regulator, consisting of the input and output capacitor grounds and the diode ground. Connect all these together with short, wide traces or a small ground plane. Similarly, create a power ground island (PGND) for the step-up regulator, consisting of the input and output capacitor grounds and the PGND pin. Create a power ground island (CPGND) for the positive and negative charge pumps, consisting of SUPP and output (VGH, VGOFF) capacitor grounds, and negative charge-pump diode ground. Connect the step-down regulator ground plane, PGND ground plane, and CPGND ground plane together with wide traces. Maximizing the width of the power ground traces improves efficiency and reduces output voltage ripple and noise spikes.
- Create an analog ground plane (GND) consisting of the GND pin, all the feedback divider ground connections, the COMP, SS, and DLY1 capacitor ground connections, and the device's exposed backside pad. Connect the PGND and GND islands by connecting the two ground pins directly to the exposed backside pad. Make no other connections between these separate ground planes.
- Place all feedback voltage-divider resistors as close as possible to their respective feedback pins. The divider's center trace should be kept short. Placing the resistors far away causes their FB traces to become antennas that can pick up switching noise. Care should be taken to avoid running any feedback trace near LX1, LX2, DRVP, or DRVN.
- Place IN2 pin, VL pin, REF pin, and VREF_O pin bypass capacitors as close as possible to the device. The ground connection of the VL bypass capacitor should be connected directly to the GND pin with a wide trace.

## Multi-Output Power Supplies with VCOM Amplifier and High-Voltage Gamma Reference for LCD TVs

- Minimize the length and maximize the width of the traces between the output capacitors and the load for best transient responses.
- Minimize the size of the LX1 and LX2 nodes while keeping them wide and short. Keep the LX1 and LX2 nodes away from feedback nodes (FB1, FB2, FBP, FBN, and VREF_FB) and analog ground. Use DC traces as shield if necessary.
Refer to the MAX17126 evaluation kit for an example of proper board layout.
