

# Rail-to-Rail, Input and Output, Instrumentation Amplifier

## FEATURES

- **116dB CMRR Independent of Gain**
- **Maximum Offset Voltage: 100 $\mu$ V**
- **Maximum Offset Voltage Drift: 250nV/ $^{\circ}$ C**
- **-40 $^{\circ}$ C to 125 $^{\circ}$ C Operation**
- Rail-to-Rail Input Range
- Rail-to-Rail Output Swing
- Supply Operation: 2.7V to 5.5V
- Available in MS8 and 3mm  $\times$  3mm  $\times$  0.8mm DFN Packages

## APPLICATIONS

- Thermocouple Amplifiers
- Electronic Scales
- Medical Instrumentation
- Strain Gauge Amplifiers
- High Resolution Data Acquisition

## DESCRIPTION

The LTC<sup>®</sup>6800 is a precision instrumentation amplifier. The CMRR is typically 116dB with a single 5V supply and is independent of gain. The input offset voltage is guaranteed below 100 $\mu$ V with a temperature drift of less than 250nV/ $^{\circ}$ C. The LTC6800 is easy to use; the gain is adjustable with two external resistors, like a traditional op amp.

The LTC6800 uses charge balanced sampled data techniques to convert a differential input voltage into a single ended signal that is in turn amplified by a zero-drift operational amplifier.

The differential inputs operate from rail-to-rail and the single ended output swings from rail-to-rail. The LTC6800 is available in an MS8 surface mount package. For space limited applications, the LTC6800 is available in a 3mm  $\times$  3mm  $\times$  0.8mm dual fine pitch leadless package (DFN).

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** These parameters are guaranteed by design. Thermocouple effects preclude measurement of these voltage levels in high speed automatic test systems.  $V_{\text{OS}}$  is measured to a limit determined by test equipment capability.

## ELECTRICAL CHARACTERISTICS

**Note 3:** If the total source resistance is less than 10k, no DC errors result from the input bias currents or the mismatch of the input bias currents or the mismatch of the resistances connected to -IN and +IN.

**Note 4:** The CMRR with a voltage gain,  $A_V$ , larger than 10 is 120dB (typ).

**Note 5:** At temperatures above 70°C, the common mode rejection ratio lowers when the common mode input voltage is within 100mV of the supply rails.

**Note 6:** The power supply rejection ratio (PSRR) measurement accuracy depends on the proximity of the power supply bypass capacitor to the device under test. Because of this, the PSRR is 100% tested to relaxed limits at final test. However, their values are guaranteed by design to meet the data sheet limits.

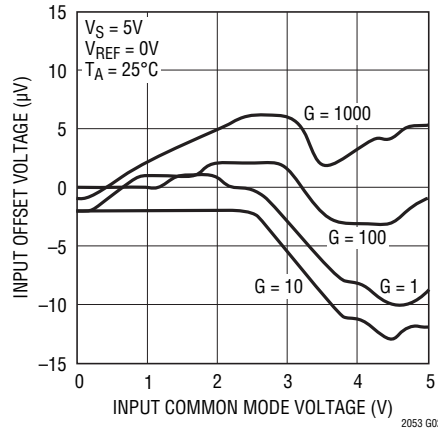

**Note 7:** The LTC6800H is guaranteed functional over the operating temperature range of -40°C to 125°C. Specifications over the -40°C to 125°C range (denoted by ●) are assured by design and characterization but are not tested or QA sampled at these temperatures.

## BLOCK DIAGRAM

## APPLICATIONS INFORMATION

### Theory of Operation

The LTC6800 uses an internal capacitor ( $C_S$ ) to sample a differential input signal riding on a DC common mode voltage (see the Block Diagram). This capacitor's charge is transferred to a second internal hold capacitor ( $C_H$ ) translating the common mode of the input differential signal to that of the REF pin. The resulting signal is amplified by a zero-drift op amp in the noninverting configuration. The RG pin is the negative input of this op amp and allows external programmability of the DC gain. Simple filtering can be realized by using an external capacitor across the feedback resistor.

### Input Voltage Range

The input common mode voltage range of the LTC6800 is rail-to-rail. However, the following equation limits the size of the differential input voltage:

$$V^- \leq (V_{+IN} - V_{-IN}) + V_{REF} \leq V^+ - 1.3$$

Where  $V_{+IN}$  and  $V_{-IN}$  are the voltages of the +IN and -IN pins, respectively,  $V_{REF}$  is the voltage at the REF pin and  $V^+$  is the positive supply voltage.

For example, with a 3V single supply and a 0V to 100mV differential input voltage,  $V_{REF}$  must be between 0V and 1.6V.

### Settling Time

The sampling rate is 3kHz and the input sampling period during which  $C_S$  is charged to the input differential voltage  $V_{IN}$  is approximately 150 $\mu$ s. First assume that on each input sampling period,  $C_S$  is charged fully to  $V_{IN}$ . Since  $C_S = C_H (= 1000\text{pF})$ , a change in the input will settle to N bits of accuracy at the op amp noninverting input after N clock cycles or 333 $\mu$ s(N). The settling time at the OUT pin is also affected by the settling of the internal op amp. Since the gain bandwidth of the internal op amp is typically 200kHz, the settling time is dominated by the switched capacitor front end for gains below 100 (see the Typical Performance Characteristics section).

## APPLICATIONS INFORMATION

Figure 1

## Input Current

Whenever the differential input  $V_{IN}$  changes,  $C_H$  must be charged up to the new input voltage via  $C_S$ . This results in an input charging current during each input sampling period. Eventually,  $C_H$  and  $C_S$  will reach  $V_{IN}$  and, ideally, the input current would go to zero for DC inputs.

In reality, there are additional parasitic capacitors which disturb the charge on  $C_S$  every cycle even if  $V_{IN}$  is a DC voltage. For example, the parasitic bottom plate capacitor on  $C_S$  must be charged from the voltage on the REF pin to the voltage on the  $-IN$  pin every cycle. The resulting input charging current decays exponentially during each input sampling period with a time constant equal to  $R_S C_S$ . **If the voltage disturbance due to these currents settles before the end of the sampling period, there will be no errors due to source resistance or the source resistance mismatch between  $-IN$  and  $+IN$ . With  $R_S$  less than 10k, no DC errors occur due to this input current.**

In the Typical Performance Characteristics section of this data sheet, there are curves showing the additional error from nonzero source resistance in the inputs. If there are no large capacitors across the inputs, the amplifier is less sensitive to source resistance and source resistance mismatch. When large capacitors are placed across the inputs, the input charging currents previously described result in larger DC errors, especially with source resistor mismatches.

## Power Supply Bypassing

The LTC6800 uses a sampled data technique and, therefore, contains some clocked digital circuitry. It is, therefore, sensitive to supply bypassing. A 0.1 $\mu$ F ceramic capacitor must be connected between Pin 8 (V<sup>+</sup>) and Pin 4 (V<sup>-</sup>) with leads as short as possible.

**TYPICAL APPLICATIONS**

**Precision  $\div 2$**

**Precision Doubler (General Purpose)**

**Precision Inversion (General Purpose)**

## PACKAGE DESCRIPTION
