

LM25010, LM25010-Q1 42-V, 1-A Step-Down Switching Regulator

1 Features

- LM25010-Q1 Qualified for Automotive Applications
- AEC-Q100 Qualified With the Following Results:
 - Device Temperature Grade 1: –40°C to 125°C Ambient Operating Temperature Range
 - Device Temperature Grade 0: –40°C to 150°C Ambient Operating Temperature Range
 - Device HBM ESD Classification Level 2
 - Device CDM ESD Classification Level C5
- Wide 6-V to 42-V Input Voltage Range
- Valley Current Limiting at 1.25 A
- Programmable Switching Frequency Up To 1 MHz
- Integrated N-Channel Buck Switch
- Integrated High Voltage Bias Regulator
- No Loop Compensation Required
- Ultra-Fast Transient Response
- Nearly Constant Operating Frequency With Line and Load Variations
- Adjustable Output Voltage
- 2.5 V, ±2% Feedback Reference
- Programmable Soft Start
- Thermal Shutdown

2 Applications

- Non-Isolated Telecommunications Regulators
- Secondary Side Post Regulators
- Automotive Electronics

3 Description

The LM25010 features all the functions needed to implement a low-cost, efficient, buck regulator capable of supplying in excess of 1-A load current. This high voltage regulator integrates an N-Channel Buck Switch, and is available in thermally enhanced 10-pin WSON and 14-pin HTSSOP packages. The constant ON-time regulation scheme requires no loop compensation resulting in fast load transient response and simplified circuit implementation. The operating frequency remains constant with line and load variations due to the inverse relationship between the input voltage and the ON-time. The valley current limit detection is set at 1.25 A. Additional features include: VCC undervoltage lockout, thermal shutdown, gate drive undervoltage lockout, and maximum duty cycle limiter.

Device Information⁽¹⁾

PART NUMBER	PACKAGE	BODY SIZE (NOM)
LM25010x	WSON (10)	4.00 mm × 4.00 mm
	HTSSOP (14)	4.40 mm × 5.00 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

5 Pin Configuration and Functions

Pin Functions

NAME	PIN		I/O	DESCRIPTION
	WSON	HTSSOP		
BST	2	3	I	Boost pin for bootstrap capacitor. Connect a capacitor from SW to the BST pin. The capacitor is charged from VCC through an internal diode during the buck switch OFF-time.
EP	—	—	—	Exposed metal pad on the underside of the device. It is recommended to connect this pad to the PC board ground plane to aid in heat dissipation.
FB	6	9	I	Voltage feedback input from the regulated output. Input to both the regulation and overvoltage comparators. The FB pin regulation level is 2.5 V.
I _{SEN}	3	4	I	Current sense. During the buck switch OFF-time, the inductor current flows through the internal sense resistor, and out of the I _{SEN} pin to the free-wheeling diode. The current limit comparator keeps the buck switch off if the I _{SEN} current exceeds 1.25 A (typical).
NC	—	1, 7, 8, 14	—	No internal connection. Can be connected to ground plane to improve heat dissipation.
R _{ON} /SD	8	11	I	ON-time control and shutdown. An external resistor from VIN to the R _{ON} /SD pin sets the buck switch ON-time. Grounding this pin shuts down the regulator.
RTN	5	6	—	Ground return for all internal circuitry other than the current sense resistor.
S _{GND}	4	5	—	Current sense ground. Recirculating current flows into this pin to the current sense resistor.
SS	7	10	I	Soft start. An internal 11.5-μA current source charges the SS pin capacitor to 2.5 V to softstart the reference input of the regulation comparator.
SW	1	2	O	Switching node. Internally connected to the buck switch source. Connect to the inductor, free-wheeling diode, and bootstrap capacitor.
VCC	9	12	I	Output of the bias regulator. The voltage at VCC is nominally equal to V _{IN} for V _{IN} < 8.9 V, and regulated at 7 V for V _{IN} > 8.9 V. Connect a 0.47-μF, or larger capacitor from VCC to ground, as close as possible to the pins. An external voltage can be applied to this pin to reduce internal dissipation if V _{IN} is greater than 8.9 V. MOSFET body diodes clamp VCC to V _{IN} if V _{CC} > V _{IN} .
VIN	10	13	I	Input supply. Nominal input range is 6 V to 42 V. Input bypass capacitors should be located as close as possible to the VIN and RTN pins.

6 Specifications

6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

	MIN	MAX	UNIT
V _{IN} to RTN	-0.3	45	V
BST to RTN	-0.3	59	V
SW to RTN (steady state)		-1.5	V
BST to VCC		45	V
BST to SW		14	V
VCC to RTN	-0.3	14	V
SGND to RTN	-0.3	0.3	V
SS to RTN	-0.3	4	V
V _{IN} to SW		45	V
All other inputs to RTN	-0.3	7	V
Lead temperature (soldering, 4 s) ⁽²⁾		260	°C
Junction temperature, T _J (LM25010, Q1, Q0)	-40	150	°C
Storage temperature, T _{stg}	-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Ratings*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) For detailed information on soldering plastic HTSSOP and WSON packages, see *Mechanical, Packaging, and Orderable Information*.

6.2 ESD Ratings: LM25010

		VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±750

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 ESD Ratings: LM25010-Q1, LM25010-Q0

		VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human-body model (HBM), per AEC Q100-002 ⁽¹⁾⁽²⁾	±2000
		Charged-device model (CDM), per AEC Q100-011 ⁽³⁾	±750

- (1) AEC Q100-002 indicates that HBM stressing shall be in accordance with the ANSI/ESDA/JEDEC JS-001 specification.
- (2) Level listed above is the passing level per ANSI/ESDA/JEDEC JS-001. JEDEC document JEP155 states that 500 V HBM allows safe manufacturing with a standard ESD control process.
- (3) Level listed above is the passing level per EIA-JEDEC JESD22-C101. JEDEC document JEP157 states that 250 V CDM allows safe manufacturing with a standard ESD control process.

6.4 Recommended Operating Ratings

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V _{IN}	Input voltage	6		42	V
I _O	Output current			1	A
Ext-V _{CC}	External bias voltage	8		13	V
T _J	Junction temperature	LM25010		125	°C
		LM25010-Q1, LM25010-Q0		150	°C

6.5 Thermal Information

THERMAL METRIC ⁽¹⁾		LM25010, LM25010-Q1		UNIT
		DPR (WSON)	PWP (HTSSOP)

7 Detailed Description

7.1 Overview

The LM25010 step-down switching regulator features all the functions needed to implement a low cost, efficient buck DC-DC converter capable of supplying in excess of 1 A to the load. This high voltage regulator integrates an N-Channel buck switch, with an easy to implement constant ON-time controller. It is available in the thermally enhanced WSON and HTSSOP packages. The regulator compares the feedback voltage to a 2.5-V reference to control the buck switch, and provides a switch ON-time which varies inversely with V_{IN} . This feature results in the operating frequency remaining relatively constant with load and input voltage variations. The switching frequency can range from less than 100 kHz to 1 MHz. The regulator requires no loop compensation resulting in very fast load transient response. The valley current limit circuit holds the buck switch off until the free-wheeling inductor current falls below the current limit threshold, nominally set at 1.25 A.

The LM25010 can be applied in numerous applications to efficiently step-down higher DC voltages. Features include: thermal shutdown, V_{CC} undervoltage lockout, gate drive undervoltage lockout, and maximum duty cycle limit.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Control Circuit Overview

The LM25010 employs a control scheme based on a comparator and a one-shot ON timer, with the output voltage feedback (FB) compared to an internal reference (2.5 V). If the FB voltage is below the reference the buck switch is turned on for a time period determined by the input voltage and a programming resistor (R_{ON}). Following the ON-time the switch remains off for a fixed 260-ns OFF-time, or until the FB voltage falls below the reference, whichever is longer. The buck switch then turns on for another ON-time period. Referring to the [Functional Block Diagram](#), the output voltage is set by R1 and R2. The regulated output voltage is calculated with [Equation 1](#).

$$V_{OUT} = 2.5 \text{ V} \times (R1 + R2) / R2 \quad (1)$$

Feature Description (continued)

The LM25010 requires a minimum of 25-mV of ripple voltage at the FB pin for stable fixed-frequency operation. If the output capacitor's ESR is insufficient, additional series resistance may be required (R3 in the [Functional Block Diagram](#)).

The LM25010 operates in continuous conduction mode at heavy load currents, and discontinuous conduction mode at light load currents. In continuous conduction mode current always flows through the inductor, never decaying to zero during the OFF-time. In this mode the operating frequency remains relatively constant with load and line variations. The minimum load current for continuous conduction mode is one-half the inductor's ripple current amplitude. Calculate the operating frequency in the continuous conduction mode with [Equation 2](#).

$$F_S = \frac{V_{OUT} \times (V_{IN} - 1.4V)}{1.18 \times 10^{-10} \times (R_{ON} + 1.4 \text{ k}\Omega) \times V_{IN}} \quad (2)$$

The buck switch duty cycle is equal to [Equation 3](#).

$$DC = \frac{t_{ON}}{t_{ON} + t_{OFF}} = t_{ON} \times F_S = \frac{V_{OUT}}{V_{IN}} \quad (3)$$

Under light load conditions, the LM25010 operates in discontinuous conduction mode, with zero current flowing through the inductor for a portion of the OFF-time. The operating frequency is always lower than that of the continuous conduction mode, and the switching frequency varies with load current. Conversion efficiency is maintained at a relatively high level at light loads because the switching losses diminish as the power delivered to the load is reduced. Calculate the approximate discontinuous mode operating frequency with [Equation 4](#).

$$F_S = \frac{V_{OUT}^2 \times L1 \times 1.4 \times 10^{20}}{R_L \times R_{ON}^2}$$

where

- R_L = the load resistance (4)

7.3.2 Start-Up Regulator (V_{CC})

A high voltage bias regulator is integrated within the LM25010. The input pin (VIN) can be connected directly to line voltages between 6 V and 42 V. Referring to the [Functional Block Diagram](#) and the graph of V_{CC} vs V_{IN} , when V_{IN} is between 6 V and the bypass threshold (nominally 8.9 V), the bypass switch (Q2) is on, and V_{CC} tracks V_{IN} within 100 mV to 150 mV. The bypass switch on-resistance is approximately 50 Ω , with inherent current limiting at approximately 100 mA. When V_{IN} is above the bypass threshold, Q2 is turned off, and V_{CC} is regulated at 7 V. The V_{CC} regulator output current is limited at approximately 15 mA. When the LM25010 is shutdown using the RON/SD pin, the V_{CC} bypass switch is shut off, regardless of the voltage at VIN.

When V_{IN} exceeds the bypass threshold, the time required for Q2 to shut off is approximately 2 μ s to 3 μ s. The capacitor at VCC (C3) must be a minimum of 0.47 μ F to prevent the voltage at VCC from rising above its absolute maximum rating in response to a step input applied at VIN. C3 must be located as close as possible to the LM25010 pins.

In applications with a relatively high input voltage, power dissipation in the bias regulator is a concern. An auxiliary voltage of between 7.5 V and 14 V can be diode connected to the VCC pin (D2 in [Figure 8](#)) to shut off the VCC regulator, reducing internal power dissipation. The current required into the VCC pin is shown in the Typical Performance Characteristics. Internally a diode connects VCC to VIN requiring that the auxiliary voltage be less than V_{IN} .

The turn-on sequence is shown in [Figure 1](#). When VCC exceeds the undervoltage lockout threshold (UVLO) of 5.25 V (t_1 in [Figure 1](#)), the buck switch is enabled, and the SS pin is released to allow the softstart capacitor (C6) to charge up. The output voltage V_{OUT} is regulated at a reduced level which increases to the desired value as the softstart voltage increases (t_2 in [Figure 1](#)).

Feature Description (continued)

Figure 8. Self-Biased Configuration

7.3.3 Regulation Comparator

The feedback voltage at the FB pin is compared to the voltage at the SS pin (2.5 V, $\pm 2\%$). In normal operation an ON-time period is initiated when the voltage at FB falls below 2.5 V. The buck switch conducts for the ON-time programmed by R_{ON} , causing the FB voltage to rise above 2.5 V. After the ON-time period the buck switch remains off until the FB voltage falls below 2.5 V. Input bias current at the FB pin is less than 5 nA over temperature.

7.3.4 Overvoltage Comparator

The feedback voltage at FB is compared to an internal 2.9 V reference. If the voltage at FB rises above 2.9 V the ON-time is immediately terminated. This condition can occur if the input voltage, or the output load, changes suddenly. The buck switch remains off until the voltage at FB falls below 2.5 V.

7.3.5 ON-Time Control

The ON-time of the internal buck switch is determined by the R_{ON} resistor and the input voltage (V_{IN}), and is calculated with [Equation 5](#).

$$t_{ON} = \frac{1.18 \times 10^{-10} \times (R_{ON} + 1.4k)}{(V_{IN} - 1.4V)} + 67 \text{ ns} \quad (5)$$

The R_{ON} resistor can be determined from the desired ON-time by re-arranging [Equation 5](#) to [Equation 6](#).

$$R_{ON} = \frac{(t_{ON} - 67 \text{ ns}) \times (V_{IN} - 1.4V)}{1.18 \times 10^{-10}} - 1.4 \text{ k}\Omega \quad (6)$$

To set a specific continuous conduction mode switching frequency (F_s), the R_{ON} resistor is determined from [Equation 7](#).

$$R_{ON} = \frac{V_{OUT} \times (V_{IN} - 1.4V)}{V_{IN} \times F_s \times 1.18 \times 10^{-10}} - 1.4 \text{ k}\Omega \quad (7)$$

In high frequency applications the minimum value for t_{ON} is limited by the maximum duty cycle required for regulation and the minimum OFF-time of the LM25010 (260 ns, $\pm 15\%$). The fixed OFF-time limits the maximum duty cycle achievable with a low voltage at V_{IN} . The minimum allowed ON-time to regulate the desired V_{OUT} at the minimum V_{IN} is determined from [Equation 8](#).

$$t_{ON(\min)} = \frac{V_{OUT} \times 300 \text{ ns}}{(V_{IN(\min)} - V_{OUT})} \quad (8)$$

Feature Description (continued)

7.3.6 Current Limit

Current limit detection occurs during the OFF-time by monitoring the recirculating current through the internal current sense resistor (R_{SENSE}). The detection threshold is 1.25 A, ± 0.25 A. Referring to the [Functional Block Diagram](#), if the current into SGND during the OFF-time exceeds the threshold level the current limit comparator delays the start of the next ON-time period. The next ON-time starts when the current into SGND is below the threshold and the voltage at FB is below 2.5 V. [Figure 9](#) illustrates the inductor current waveform during normal operation and during current limit. The output current I_O is the average of the inductor ripple current waveform. The Low Load Current waveform illustrates continuous conduction mode operation with peak and valley inductor currents below the current limit threshold. When the load current is increased (High Load Current), the ripple waveform maintains the same amplitude and frequency since the current falls below the current limit threshold at the valley of the ripple waveform. Note the average current in the High Load Current portion of [Figure 9](#) is above the current limit threshold. Since the current reduces below the threshold in the normal OFF-time each cycle, the start of each ON-time is not delayed, and the circuit's output voltage is regulated at the correct value. When the load current is further increased such that the lower peak would be above the threshold, the OFF-time is lengthened to allow the current to decrease to the threshold before the next ON-time begins (Current Limited portion of [Figure 9](#)). Both V_{OUT} and the switching frequency are reduced as the circuit operates in a constant current mode. The load current (I_{OCL}) is equal to the current limit threshold plus half the ripple current ($\Delta I/2$). The ripple amplitude (ΔI) is calculated from [Equation 9](#).

$$\Delta I = \frac{(V_{IN} - V_{OUT}) \times t_{ON}}{L1} \quad (9)$$

The current limit threshold can be increased by connecting an external resistor (R_{CL}) between SGND and ISEN. R_{CL} typically is less than 1 Ω , and the calculation of its value is explained in [Application and Implementation](#). If the current limit threshold is increased by adding R_{CL} , the maximum continuous load current should not exceed 1.5 A, and the peak current out of the SW pin should not exceed 2 A.

Figure 9. Inductor Current - Current Limit Operation

7.3.7 Soft Start

The soft-start feature allows the regulator to gradually reach a steady-state operating point, thereby reducing start-up stresses and current surges. At turnon, while V_{CC} is below the undervoltage threshold (t_1 in [Figure 1](#)), the SS pin is internally grounded, and V_{OUT} is held at 0 V. When V_{CC} exceeds the undervoltage threshold (UVLO) an internal 11.5- μ A current source charges the external capacitor (C6) at the SS pin to 2.5 V (t_2 in [Figure 1](#)). The increasing SS voltage at the non-inverting input of the regulation comparator gradually increases the output voltage from zero to the desired value. The soft-start feature keeps the load inductor current from reaching the current limit threshold during start-up, thereby reducing inrush currents.

An internal switch grounds the SS pin if V_{CC} is below the undervoltage lockout threshold, or if the circuit is shutdown using the RON/SD pin.

Feature Description (continued)

7.3.8 N-Channel Buck Switch and Driver

The LM25010 integrates an N-Channel buck switch and associated floating high voltage gate driver. The peak current through the buck switch should not exceed 2A, and the load current should not exceed 1.5A. The gate driver circuit is powered by the external bootstrap capacitor between BST and SW (C4), which is recharged each OFF-time from V_{CC} through the internal high voltage diode. The minimum OFF-time, nominally 260 ns, ensures sufficient time during each cycle to recharge the bootstrap capacitor. A 0.022 μ F ceramic capacitor is recommended for C4.

7.3.9 Thermal Shutdown

The LM25010 should be operated below the maximum operating junction temperature rating. If the junction temperature increases during a fault or abnormal operating condition, the internal Thermal Shutdown circuit activates typically at 175°C. The Thermal Shutdown circuit reduces power dissipation by disabling the buck switch and the ON timer. This feature helps prevent catastrophic failures from accidental device overheating. When the junction temperature reduces below approximately 155°C (20°C typical hysteresis), normal operation resumes.

7.4 Device Functional Modes

7.4.1 Shutdown

The LM25010 can be remotely shut down by forcing the RON/SD pin below 0.7 V with a switch or open drain device. See [Figure 10](#). In the shutdown mode the SS pin is internally grounded, the ON-time one-shot is disabled, the input current at VIN is reduced, and the V_{CC} bypass switch is turned off. The V_{CC} regulator is not disabled in the shutdown mode. Releasing the RON/SD pin allows normal operation to resume. The nominal voltage at RON/SD is shown in [Figure 6](#). When switching the RON/SD pin, the transition time should be faster than one to two cycles of the regulator's nominal switching frequency.

Figure 10. Shutdown Implementation

8 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The LM25010 is a non-synchronous buck regulator converter designed to operate over a wide input voltage and output current range. Spreadsheet-based calculator tools, available on the TI product website at [Quick-Start Calculator](#), can be used to design a single output non-synchronous buck converter.

Alternatively, online WEBENCH® software is available to create a complete buck design and generate the bill of materials, estimated efficiency, solution size, and cost of the complete solution.

8.2 Typical Application

The final circuit is shown in [Figure 11](#), and its performance is shown in [Figure 16](#) and [Figure 17](#). Current limit measured approximately 1.3 A.

Figure 11. LM25010 Example Circuit

8.2.1 Design Requirements

Table 1 lists the operating parameters for [Figure 11](#).

Table 1. Design Parameters

PARAMETER	EXAMPLE VALUE
Input voltage	6 V to 40 V
Output voltage	5 V
Load current	200 mA to 1 A
Soft-start time	5 ms

8.2.2 Detailed Design Procedure

The procedure for calculating the external components is illustrated with a design example. Configure the circuit in [Figure 11](#) according to the components listed in [Table 2](#).

Table 2. List of Components for LM25010 Example Circuit

ITEM	DESCRIPTION	VALUE
C1	Ceramic capacitor	(2) 2.2 μ F, 50 V
C2	Ceramic capacitor	22 μ F, 16 V
C3	Ceramic capacitor	0.47 μ F, 16 V
C4, C6	Ceramic capacitor	0.022 μ F, 16 V
C5	Ceramic capacitor	0.1 μ F, 50 V
D1	Schottky diode	60 V, 2 A
L1	Inductor	100 μ H
R1	Resistor	1 k Ω
R2	Resistor	1 k Ω
R3	Resistor	1.5 Ω
R _{ON}	Resistor	200 k Ω
U1	LM25010	—

8.2.2.1 Component Selection

8.2.2.1.1 R1 and R2

These resistors set the output voltage, and calculate the ratio with [Equation 10](#).

$$R1/R2 = (V_{OUT}/2.5V) - 1 \quad (10)$$

R1/R2 calculates to 1. The resistors should be chosen from standard value resistors in the range of 1 k Ω to 10 k Ω . A value of 1 k Ω is used for R1 and R2.

8.2.2.1.2 R_{ON}, F_S

R_{ON} can be chosen using [Equation 7](#) to set the nominal frequency, or from [Equation 6](#) if the ON-time at a particular V_{IN} is important. A higher frequency generally means a smaller inductor and capacitors (value, size and cost), but higher switching losses. A lower frequency means a higher efficiency, but with larger components. Generally, if PC board space is tight, a higher frequency is better. The resulting ON-time and frequency have a $\pm 25\%$ tolerance. Using [Equation 7](#) at a nominal V_{IN} of 8 V in [Equation 11](#).

$$R_{ON} = \frac{5V \times (8V - 1.4V)}{8V \times 175 \text{ kHz} \times 1.18 \times 10^{-10}} - 1.4 \text{ k}\Omega = 198 \text{ k}\Omega \quad (11)$$

A value of 200 k Ω will be used for R_{ON}, yielding a nominal frequency of 161 kHz at V_{IN} = 6 V, and 203 kHz at V_{IN} = 40 V.

8.2.2.1.3 L1

The inductor value is determined based on the load current, ripple current, and the minimum and maximum input voltage (V_{IN(min)}, V_{IN(max)}). See [Figure 12](#).

Figure 12. Inductor Current

To keep the circuit in continuous conduction mode, the maximum allowed ripple current is twice the minimum load current, or 400 mA_{P-P}. Using this value of ripple current, the inductor (L1) is calculated using [Equation 12](#) and [Equation 13](#).

$$L1 = \frac{V_{OUT} \times (V_{IN(max)} - V_{OUT})}{I_{OR} \times F_{S(min)} \times V_{IN(max)}}$$

where

- $F_{S(min)}$ is the minimum frequency of 152 kHz (203 kHz – 25%) at $V_{IN(max)}$ (12)

$$L1 = \frac{5V \times (40V - 5V)}{0.40A \times 152 \text{ kHz} \times 40V} = 72 \mu\text{H} \quad (13)$$

[Equation 13](#) provides the minimum value for inductor L1. When selecting an inductor, use a higher standard value (100 μH). To prevent saturation, and possible destructive current levels, L1 must be rated for the peak current which occurs if the current limit and maximum ripple current are reached simultaneously (I_{PK} in [Figure 9](#)). The maximum ripple amplitude is calculated by rearranging [Equation 12](#) using $V_{IN(max)}$, $F_{S(min)}$, and the minimum inductor value, based on the manufacturer's tolerance. Assume, for [Equation 14](#), [Equation 15](#), and [Equation 16](#), the inductor's tolerance is $\pm 20\%$.

$$I_{OR(max)} = \frac{V_{OUT} \times (V_{IN(max)} - V_{OUT})}{L1_{min} \times F_{S(min)} \times V_{IN(max)}} \quad (14)$$

$$I_{OR(max)} = \frac{5V \times (40V - 5V)}{80 \mu\text{H} \times 152 \text{ kHz} \times 40V} = 360 \text{ mA}_{P-P} \quad (15)$$

$$I_{PK} = I_{LIM} + I_{OR(max)} = 1.5 \text{ A} + 0.36 \text{ A} = 1.86 \text{ A}$$

where

- I_{LIM} is the maximum current limit threshold (16)

At the nominal maximum load current of 1 A, the peak inductor current is 1.18 A.

8.2.2.1.4 R_{CL}

Since it is obvious that the lower peak of the inductor current waveform does not exceed 1 A at maximum load current (see [Figure 12](#)), it is not necessary to increase the current limit threshold. Therefore R_{CL} is not needed for this exercise. For applications where the lower peak exceeds 1 A, see [Increasing The Current Limit Threshold](#).

8.2.2.1.5 C2 and R3

Since the LM25010 requires a minimum of 25 mV_{P-P} of ripple at the FB pin for proper operation, the required ripple at V_{OUT} is increased by R1 and R2, and is equal to [Equation 17](#).

$$V_{RIPPLE} = 25 \text{ mV}_{P-P} \times (R1 + R2) / R2 = 50 \text{ mV}_{P-P} \quad (17)$$

This necessary ripple voltage is created by the inductor ripple current acting on C2's ESR + R3. First, determine the minimum ripple current, which occurs at minimum V_{IN} , maximum inductor value, and maximum frequency with [Equation 18](#).

$$\begin{aligned} I_{OR(min)} &= \frac{V_{OUT} \times (V_{IN(min)} - V_{OUT})}{L1_{max} \times F_{S(max)} \times V_{IN(min)}} \\ &= \frac{5V \times (6V - 5V)}{120 \mu\text{H} \times 201 \text{ kHz} \times 6V} = 34.5 \text{ mA}_{P-P} \end{aligned} \quad (18)$$

The minimum ESR for C2 is then equal to [Equation 19](#).

$$ESR_{(min)} = \frac{50 \text{ mV}}{34.5 \text{ mA}} = 1.45\Omega \quad (19)$$

If the capacitor used for C2 does not have sufficient ESR, R3 is added in series as shown in the [Functional Block Diagram](#). The value chosen for C2 is application dependent, and it is recommended that it be no smaller than 3.3 μF . C2 affects the ripple at V_{OUT} , and transient response. Experimentation is usually necessary to determine the optimum value for C2.

8.2.2.1.6 D1

A Schottky diode is recommended. Ultra-fast recovery diodes are not recommended as the high speed transitions at the SW pin may inadvertently affect the IC's operation through external or internal EMI. The diode should be rated for the maximum V_{IN} (40 V), the maximum load current (1 A), and the peak current which occurs when current limit and maximum ripple current are reached simultaneously (I_{PK} in [Figure 9](#)), previously calculated to be 1.86 A. The diode's forward voltage drop affects efficiency due to the power dissipated during the OFF-time. The average power dissipation in D1 is calculated from [Equation 20](#).

$$P_{D1} = V_F \times I_O \times (1 - D)$$

where

- I_O is the load current
- D is the duty cycle

(20)

8.2.2.1.7 C1

This capacitor limits the ripple voltage at VIN resulting from the source impedance of the supply feeding this circuit, and the on/off nature of the switch current into VIN. At maximum load current, when the buck switch turns on, the current into VIN steps up from zero to the lower peak of the inductor current waveform (I_{PK+} in [Figure 12](#)), ramps up to the peak value (I_{PK+}), then drops to zero at turnoff. The average current into VIN during this ON-time is the load current. For a worst case calculation, C1 must supply this average current during the maximum ON-time. The maximum ON-time is calculated at $V_{IN} = 6$ V using [Equation 5](#), with a 25% tolerance added to [Equation 21](#).

$$t_{ON(max)} = \left[\frac{1.18 \times 10^{-10} \times (200k + 1.4k)}{6V - 1.4V} + 67 \text{ ns} \right] \times 1.25 = 6.5 \mu\text{s}$$

(21)

The voltage at VIN should not be allowed to drop below 5.5 V in order to maintain V_{CC} above its UVLO in [Equation 22](#).

$$C1 = \frac{I_O \times t_{ON}}{\Delta V} = \frac{1.0A \times 6.5 \mu\text{s}}{0.5V} = 13 \mu\text{F}$$

(22)

Normally a lower value can be used for C1 since the above calculation is a worst case calculation which assumes the power source has a high source impedance. A quality ceramic capacitor with a low ESR should be used for C1.

8.2.2.1.8 C3

The capacitor at the VCC pin provides noise filtering and stability, prevents false triggering of the V_{CC} UVLO at the buck switch ON and OFF transitions, and limits the peak voltage at V_{CC} when a high voltage with a short rise time is initially applied at V_{IN} . C3 should be no smaller than 0.47 μF , and must be a good quality, low ESR, ceramic capacitor, physically close to the IC pins.

8.2.2.1.9 C4

The recommended value for C4 is 0.022 μF . TI recommends a high quality ceramic capacitor with low ESR as C4 supplies the surge current to charge the buck switch gate at each turnon. A low ESR also ensures a complete recharge during each OFF-time.

8.2.2.1.10 C5

This capacitor suppresses transients and ringing due to lead inductance at VIN. TI recommends a low ESR, 0.1- μF ceramic chip capacitor placed physically close to the LM25010.

8.2.2.1.11 C6

The capacitor at the SS pin determines the softstart time (that is the time for the reference voltage at the regulation comparator and the output voltage) to reach their final value. Determine the capacitor value with [Equation 23](#).

$$C6 = \frac{t_{SS} \times 11.5 \mu\text{A}}{2.5V}$$

(23)

For a 5 ms softstart time, C6 calculates to 0.022 μF .

8.2.2.2 Increasing The Current Limit Threshold

The current limit threshold is nominally 1.25 A, with a minimum guaranteed value of 1 A. If, at maximum load current, the lower peak of the inductor current (I_{PK-} in [Figure 12](#)) exceeds 1 A, resistor R_{CL} must be added between S_{GND} and I_{SEN} to increase the current limit threshold to be equal or exceed that lower peak current. This resistor diverts some of the recirculating current from the internal sense resistor so that a higher current level is needed to switch the internal current limit comparator. Calculate I_{PK-} with [Equation 24](#).

$$I_{PK-} = I_{O(max)} - \frac{I_{OR(min)}}{2}$$

where

- $I_{O(max)}$ is the maximum load current
 - $I_{OR(min)}$ is the minimum ripple current calculated using [Equation 18](#)
- (24)

R_{CL} is calculated with [Equation 25](#).

$$R_{CL} = \frac{1.0A \times 0.11\Omega}{I_{PK-} - 1.0A}$$

where

- 0.11 Ω is the minimum value of the internal resistance from S_{GND} to I_{SEN}
- (25)

The next smaller standard value resistor should be used for R_{CL} . With the addition of R_{CL} it is necessary to check the average and peak current values to ensure they do not exceed the LM25010 limits. At maximum load current the average current through the internal sense resistor is calculated with [Equation 26](#).

$$I_{AVE} = \frac{I_{O(max)} \times R_{CL} \times (V_{IN(max)} - V_{OUT})}{(R_{CL} + 0.11\Omega) \times V_{IN(max)}}$$
(26)

If I_{AVE} is less than 2 A, no changes are necessary. If it exceeds 2 A, R_{CL} must be reduced. The upper peak of the inductor current (I_{PK+}), at maximum load current, is calculated using [Equation 27](#).

$$I_{PK+} = I_{O(max)} + \frac{I_{OR(max)}}{2}$$

where

- $I_{OR(max)}$ is calculated using [Equation 14](#)
- (27)

If I_{PK+} exceeds 3.5 A, the inductor value must be increased to reduce the ripple amplitude. This necessitates recalculation of $I_{OR(min)}$, I_{PK-} , and R_{CL} .

When the circuit is in current limit, the upper peak current out of the SW pin is calculated with [Equation 28](#).

$$I_{PK+(CL)} = \frac{1.5A \times (150 \text{ m}\Omega + R_{CL})}{R_{CL}} + I_{OR(MAX)}$$
(28)

The inductor L1 and diode D1 must be rated for this current.

8.2.2.3 Ripple Configurations

For applications where low output voltage ripple is required the output can be taken directly from the low ESR output capacitor (C2) as shown in [Figure 13](#). However, R3 slightly degrades the load regulation. The specific component values, and the application determine if this is suitable.

Figure 13. Low Ripple Output

Where the circuit of [Figure 13](#) is not suitable, the circuits of [Figure 14](#) or [Figure 15](#) can be used.

Figure 14. Low Output Ripple Using a Feedforward Capacitor

In [Figure 14](#), C_{ff} is added across $R1$ to AC-couple the ripple at V_{OUT} directly to the FB pin. This allows the ripple at V_{OUT} to be reduced, in some cases considerably, by reducing $R3$. In the circuit of [Figure 11](#), the ripple at V_{OUT} ranged from 50 mV_{P-P} at $V_{IN} = 6$ V to 285 mV_{P-P} at $V_{IN} = 40$ V. By adding a 1000 pF capacitor at C_{ff} and reducing $R3$ to 0.75 Ω , the V_{OUT} ripple was reduced by 50%, ranging from 25 mV_{P-P} to 142 mV_{P-P}.

Figure 15. Low Output Ripple Using Ripple Injection

To reduce V_{OUT} ripple further, the circuit of [Figure 15](#) can be used. R3 has been removed, and the output ripple amplitude is determined by C2's ESR and the inductor ripple current. RA and CA are chosen to generate a 40 mV to 50 mV_{P-P} sawtooth at their junction, and that voltage is AC-coupled to the FB pin via CB. In selecting RA and CA, V_{OUT} is considered a virtual ground as the SW pin switches between V_{IN} and -1 V. Since the ON-time at SW varies inversely with V_{IN} , the waveform amplitude at the RA and CA junction is relatively constant. R1 and R2 must typically be increased to more than 5 k Ω each to not significantly attenuate the signal provided to FB through CB. Typical values for the additional components are RA = 200 k Ω , CA = 680 pF, and CB = 0.01 μ F.

8.2.3 Application Curves

8.3 Do's and Don'ts

A minimum load current of 1 mA is required to maintain proper operation. If the load current falls below that level, the bootstrap capacitor can discharge during the long OFF-time and the circuit either shuts down or cycles ON and OFF at a low frequency. If the load current is expected to drop below 1 mA in the application, choose the feedback resistors to be low enough in value to provide the minimum required current at nominal V_{OUT} .

9 Power Supply Recommendations

The LM25010 is designed to operate with an input power supply capable of supplying a voltage range from 6 V to 42 V. The input power supply must be well-regulated and capable of supplying sufficient current to the regulator during peak load operation. Also, like in all applications, the power-supply source impedance must be small compared to the module input impedance to maintain the stability of the converter.

10 Layout

10.1 Layout Guidelines

The LM25010 regulation, overvoltage, and current limit comparators are very fast, and respond to short duration noise pulses. Therefore, layout considerations are critical for optimum performance. The layout must be as neat and compact as possible, and all the components must be as close as possible to their associated pins. The two major current loops have currents which switch very fast, and so the loops should be as small as possible to minimize conducted and radiated EMI. The first loop is that formed by C1 (C_{IN}), through the VIN to SW pins, L1 (L_{IND}), C2 (C_{OUT}), and back to C1. The second loop is that formed by D1, L1, C2, and the SGND and ISEN pins. The ground connection from C2 to C1 should be as short and direct as possible, preferably without going through vias. Directly connect the SGND and RTN pin to each other, and they should be connected as directly as possible to the C1/C2 ground line without going through vias. The power dissipation within the IC can be approximated by determining the total conversion loss ($P_{IN} - P_{OUT}$), and then subtracting the power losses in the free-wheeling diode and the inductor. The power loss in the diode is approximately [Equation 29](#).

$$P_{D1} = I_O \times V_F \times (1 - D) \quad (29)$$

where I_O is the load current, V_F is the diode's forward voltage drop, and D is the duty cycle. The power loss in the inductor is approximately [Equation 30](#).

$$P_{L1} = I_O^2 \times R_L \times 1.1$$

where

- R_L is the inductor's DC resistance
 - the 1.1 factor is an approximation for the AC losses
- (30)

If it is expected that the internal dissipation of the LM25010 will produce high junction temperatures during normal operation, good use of the PC board's ground plane can help considerably to dissipate heat. The exposed pad on the IC package bottom should be soldered to a ground plane, and that plane should both extend from beneath the IC, and be connected to exposed ground plane on the board's other side using as many vias as possible. The exposed pad is internally connected to the IC substrate. The use of wide PC board traces at the pins, where possible, can help conduct heat away from the IC. The four NC pins on the HTSSOP package are not electrically connected to any part of the IC, and may be connected to ground plane to help dissipate heat from the package. Judicious positioning of the PC board within the end product, along with the use of any available air flow (forced or natural convection) can help reduce the junction temperature.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

THERMAL PAD MECHANICAL DATA

DPR (S-PWSON-N10)

PLASTIC SMALL OUTLINE NO-LEAD

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

4211551/C 12/13

NOTES: All linear dimensions are in millimeters

DPR (S-PWSON-N10)

PLASTIC SMALL OUTLINE NO-LEAD

- NOTES:
- All linear dimensions are in millimeters.
 - This drawing is subject to change without notice.
 - Publication IPC-7351 is recommended for alternate designs.
 - This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, Quad Flat-Pack Packages, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <<http://www.ti.com>>.
 - Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
 - Customers should contact their board fabrication site for recommended solder mask tolerances and via tenting recommendations for vias placed in the thermal pad.
