

LTC1287

3V Single Chip 12-Bit Data Acquisition System

FEATURES DESCRIPTIO U

- Single Supply 3.3V Operation
- Built-In Sample-and-Hold
- Direct 3-Wire Interface to Most MPU Serial Ports and All MPU Parallel Ports
- 30kHz Maximum Throughput Rate

KEY SPECIFICATIONS $\overline{}$

- Minimum Guaranteed Supply Voltage: 2.7V
- Resolution: 12 Bits
- Fast Conversion Time: 24µs Max Over Temp.
- Low Supply Current: 1.0mA

APPLICATIONS

AC CHARACTERISTICS The ● **denotes the specifications which apply over the full operating temperature range,**

otherwise specifications are at $T_A = 25^\circ \text{C}$ **. (Note 3)**

DIGITAL AND DC ELECTRICAL CHARACTERISTICS The \bullet denotes the specifications which apply over the full operating temperature range, otherwise specifications are at $T_A = 25^\circ C$. (Note 3)

Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

Note 2: All voltage values are with respect to ground (unless otherwise noted).

Note 3: $V_{CC} = 3V$, $V_{REF} = 2.5V$, $CLK = 500kHz$ unless otherwise specified. **Note 4:** One LSB is equal to V_{REF} divided by 4096. For example, when V_{REF} $= 2.5V$, $1LSB = 2.5V/4096 = 0.61mV$.

Note 5: Integral nonlinearity error is defined as the deviation of a code from a straight line passing through the actual endpoints of the transfer curve. The deviation is measured from the center of the quantization band. **Note 6:** Recommended operating conditions.

Note 7: Two on-chip diodes are tied to each analog input which will conduct for analog voltages one diode drop below GND or one diode drop above V $_{\rm CC}$. Be careful during testing at low V $_{\rm CC}$ levels, as high level analog inputs can cause this input diode to conduct, especially at elevated temperature, and cause errors for inputs near full scale. This spec allows 50mV forward bias of either diode. This means that as long as the analog input does not exceed the supply voltage by more than 50mV, the output code will be correct.

Note 8: Channel leakage current is measured after the channel selection.

Note 9: Increased leakage currents at elevated temperatures cause the S/H to droop, therefore it is recommended that $f_{CLK} \geq 30$ kHz at 85°C and $f_{CLK} \geq 3$ kHz at 25°C.

MAXIMUM CLK FREQUENCY REPRESENTS THE CLK FREQUENCY AT WHICH A 0.1LSB SHIFT IN THE ERROR AT ANY CODE TRANSITION FROM ITS 500kHz VALUE IS FIRST DETECTED. AS THE CLK FREQUENCY IS DECREASED FROM 1MHz, MINIMUM CLK FREQUENCY (∆ERROR ≤ 0.1LSB) REPRESENTS THE FREQUENCY AT WHICH A 0.1LSB SHIFT IN ANY CODE TRANSITION FROM ITS 500kHz VALUE IS FIRST DETECTED.

CHANGE IN FULL SCALE ERROR FROM ITS VALUE AT $R_{\text{FILTER}} = 0$ IS FIRST DETECTED.

PIN FUNCTIONS

CS (Pin 1): Chip Select Input. A logic low on this input enables the LTC1287.

+IN, –IN (Pin 2,3): Analog Inputs. These inputs must be free of noise with respect to GND.

GND (Pin 4): Analog Ground GND should be tied directly to an analog ground plane.

VREF (Pin 5): Reference Input. The reference input defines the span of the A/D converter and must be kept free of noise with respect to GND.

D_{OUT} (Pin 6): Digital Data Output. The A/D conversion result is shifted out of this output.

CLK (Pin 7): Shift Clock. This clock synchronizes the serial data transfer.

V_{CC} (Pin 8): Positive Supply. This supply must be kept free of noise and ripple by bypassing directly to the analog ground plane.

U A S O PPLICATI W U U I FOR ATIO

The LTC1287 is a data acquisition component which contains the following functional blocks:

- 1. 12-bit successive approximation capacitive A/D converter
- 2. Analog multiplexer (MUX)
- 3. Sample-and-hold (S/H)
- 4. Synchronous, half-duplex serial interface
- 5. Control and timing logic

DIGITAL CONSIDERATIONS

Serial Interface

The LTC1287 communicates with microprocessors and other external circuitry via a synchronous, half-duplex, three-wire serial interface (see Operating Sequence). The clock (CLK) synchronizes the data transfer with each bit being transmitted on the falling CLK edge. The LTC1287 does not require a configuration input word and has no D_{IN} pin. It is permanently configured to have a single differential input and to operate in unipolar mode. A falling \overline{CS} initiates data transfer. The first CLK pulse enables D_{OUT} . After one null bit, the A/D conversion result is output on the D_{OUT} line with a MSB-first sequence followed by a LSBfirst sequence. With the half duplex serial interface the D_{OUT} data is from the current conversion. This provides easy interface to MSB- or LSB-first serial ports. Bringing \overline{CS} high resets the LTC1287 for the next data exchange.

Logic Levels

The logic level standards for this supply range have not been well defined. What standards that do exist are not universally accepted. The trip point on the logic inputs of the LTC1287 is $0.28 \times V_{CC}$. This makes the logic inputs compatible with HC-type levels and processors that are

7

specified at 3.3V. The output D_{OUT} is also compatible with the above standards. The following summarizes such levels.

The LTC1287 can be driven with 5V logic even when V_{CC} is at 3.3V. This is due to a unique input protection device that is found on the LTC1287.

Microprocessor Interfaces

The LTC1287 can interface directly (without external hardware) to most popular microprocessor (MPU) synchronous serial formats. If an MPU without a serial interface is used, then three of the MPU's parallel port lines can be programmed to form the serial link to the LTC1287. Many of the popular MPUs can operate with 3V supplies. For example the MC68HC11 is an MPU with a serial format (SPI). Likewise parallel MPUs that have the 8051 type architecture are also capable of operating at this voltage range. The code for these processors remains the same and can be found in the LTC1292 data sheet.

Sharing the Serial Interface

The LTC1287 can share the same two-wire serial interface with other peripheral components or other LTC1287s (Figure 2). In this case, the \overline{CS} signals decide which LTC1287 is being addressed by the MPU.

ANALOG CONSIDERATIONS Grounding

The LTC1287 should be used with an analog ground plane and single point grounding techniques. Do not use wire wrapping techniques to breadboard and evaluate the device. To achieve the optimum performance use a PC board. The ground pin (Pin 4) should be tied directly to the ground plane with minimum lead length (a low profile socket is fine). Pin 7 (V_{CC}) should be bypassed to the ground plane with a 22µF (minimum value) tantalum with leads as short as possible and as close as possible to the pin. A 0.1μ F ceramic disk also should be placed in parallel with the 22µF and again with leads as short as possible and as close to V_{CC} as possible. Figure 3 shows an example of an ideal LTC1287 ground plane design for a two-sided board. Of course this much ground plane will not always be possible, but users should strive to get as close to this ideal as possible.

Bypassing

For good performance, V_{CC} must be free of noise and ripple. Any changes in the V_{CC} voltage with respect to ground during a conversion cycle can induce errors or noise in the output code. V_{CC} noise and ripple can be kept below 0.5mV by bypassing the V_{CC} pin directly to the analog plane with a minimum of 22µF tantalum capacitor and with leads as short as possible. The lead from the device to the V_{CC} supply also should be kept to a minimum and the V_{CC} supply should have a low output impedance

Figure 2. Several LTC1287s Sharing One 2-Wire Serial Interface Figure 3. Example Ground Plane for the LTC1287

such as obtained from a voltage regulator (e.g., LT1117). For high frequency bypassing a 0.1µF ceramic disk placed in parallel with the 22µF is recommended. Again the leads should be kept to a minimum. Using a battery to power the LTC1287 will help reduce the amount of bypass capacitance required on the V_{CC} pin. A battery placed close to the device will only require 10µF to adequately bypass the supply pin. Figure 4 shows the effect of poor V_{CC} bypassing. Figure 5 shows the settling of a LT1117 low dropout regulator with a 22µF bypass capacitor. The noise and ripple is kept around 0.5mV. Figure 6 shows the response of a lithium battery with a 10µF bypass capacitor. The noise and ripple is kept below 0.5mV.

Analog Inputs

Because of the capacitive redistribution A/D conversion techniques used, the analog inputs of the LTC1287 have

Figure 4. Poor V_{CC} Bypassing. Noise and **Ripple Can Cause A/D Errors**

Figure 5. LT1117 Regulator with 22µF Bypassing on V_{CC}

Figure 6. Lithium Battery with 10µF Bypassing on V_{CC}

capacitive switching input current spikes. These current spikes settle quickly and do not cause a problem. If large source resistances are used or if slow settling op amps drive the inputs, take care to insure the transients caused by the current spikes settle completely before the conversion begins.

Source Resistance

The analog inputs of the LTC1287 look like a 100pF capacitor (C_{IN}) in series with a 1.5k resistor (R_{ON}). This value for R_{ON} is for V_{CC} = 2.7V. With larger supply voltages R_{ON} will be reduced. For example, with $V_{CC} = 2.7V$ and V⁻ $=-2.7V$, R_{ON} becomes 500 Ω . C_{IN} gets switched between (+) and (–) inputs once during each conversion cycle. Large external source resistors and capacitances will slow the settling of the inputs. It is important that the overall RC time constant is short enough to allow the analog inputs to settle completely within the allowed time.

Figure 7. Analog Input Equivalent Circuit

"+" Input Settling

The input capacitor is switched onto the "+" input during the sample phase $(t_{SMPL},$ see Figures 8a, 8b and 8c). The sample period can be as short as $t_{WH\overline{CS}}$ + 0.5 CLK cycle or as long as t_{WHCS} + 1.5 CLK cycles before a conversion starts. This variability depends on where \overline{CS} falls relative to CLK. The voltage on the "+" input must settle completely within the sample period. Minimizing R_{SOLIRCF} + and C1 will improve the settling time. If large "+" input source resistance must be used, the sample time can be increased by using a slower CLK frequency. With the minimum possible sample time of 6.0µs, R_{SOLIRCF} < 4.0k and C1 **< 20pF will provide adequate settle time.**

"–" Input Settling

At the end of the sample phase the input capacitor switches to the "–" input and the conversion starts (see Figures 8a, 8b and 8c). During the conversion, the "+" input voltage is

1287fa

10

Figure 8c. Setup Time (t_{SUCS}) is Not Met

effectively "held" by the sample and hold and will not affect the conversion result. It is critical that the "–" input voltage be free of noise and settle completely during the first CLK cycle of the conversion. Minimizing $R_{SOLIRCF}$ and C2 will improve settling time. If large "–" input source resistance must be used the time can be extended by using a slower CLK frequency. At the maximum CLK frequency of 500kHz, **RSOURCE– < 200**Ω **and C2 < 20pF will provide adequate settling.**

Input Op Amps

When driving the analog inputs with an op amp it is important that the op amp settles within the allowed time (see Figures 8a, 8b and 8c). Again the "+" and "–" input sampling times can be extended as described above to accommodate slower op amps. For single supply low voltage application the LT1797 and LT1677 can be made to settle well even with the minimum settling windows of $6\mu s$ ("+" input) and $2\mu s$ ("-" input) which occur at the maximum clock rates (CLK = 500kHz). Figures 9 and 10 show examples of adequate and poor op amp settling. The LT1077, LT1078 or LT1079 can be used here to reduce power consumption. Placing an RC network at the output of the op amps will inprove the settling response and also reduce the broadband noise.

Figure 10. Poor Op Amp Settling Can Cause A/D Errors

APPLICATIONS INFORMATION

RC Input filtering

It is possible to filter the inputs with an RC network as shown in Figure 11. For large values of C_F (e.g., 1 μ F) the capacitive input switching currents are averaged into a net DC current. A filter should be chosen with a small resistor and large capacitor to prevent DC drops across the resistor. The magnitude of the DC current is approximately I_{DC} = 100pF \times V_{IN}/t_{CYC} and is roughly proportional to V_{IN}. When running at the minimum cycle time of 33µs, the input current equals 7.6 μ A at V_{IN} = 2.5V. Here a filter resistor of 8Ω will cause 0.1LSB of full-scale error. If a large filter resistor must be used, errors can be reduced by increasing the cycle time as shown in the Typical Performance Characteristics curve Maximum Filter Resistor vs Cycle Time.

Figure 11. RC Input Filtering

Input Leakage Current

Input leakage currents also can create errors if the source resistance gets too large. For example, the maximum input leakage specification of 1μ A (at 85 \degree C) flowing through a source resistance of 1k will cause a voltage drop of 1mV or 1.6LSB with $V_{\text{RFF}} = 2.5V$. This error will be much reduced at lower temperatures because leakage drops rapidly (see Typical Performance Characteristics curve Input Channel Leakage Current vs Temperature).

SAMPLE-AND-HOLD

Single-Ended Input

The LTC1287 provides a built-in sample and hold (S&H) function on the +IN input for signals acquired in the single ended mode (–IN pin grounded). The sample and hold allows the LTC1287 to convert rapidly varying signals (see Typical Performance Characteristics curve of S&H Acquisition Time vs Source Resistance). The input voltage is sampled during the t_{SMP1} time as shown in Figure 8. The sampling interval begins at rising edge of CS and continues until the falling edge of the CLK before the conversion begins. On this falling edge the S&H goes into the hold mode and the conversion begins.

Differential Input

With a differential input the A/D no longer converts a single voltage but converts the difference between two voltages. The voltage on the +IN pin is sampled and held and can be rapidly time varying. The voltage on the –IN pin must remain constant and be free of noise and ripple throughout the conversion time. Otherwise the differencing operation will not be done accurately. The conversion time is 12 CLK cycles. Therefore a change in the –IN input voltage during this interval can cause conversion errors. For a sinusoidal voltage on the –IN input this error would be:

$$
V_{ERROR(MAX)} = \left(2\pi f_{(-IN)}V_{PEAK}\right)\left(\frac{12}{f_{CLK}}\right)
$$

Where $f_{(-|N)}$ is the frequency of the $-N$ input voltage, V_{PEAK} is its peak amplitude and f_{CLK} is the frequency of the CLK. Usually V_{ERROR} will not be significant. For a 60Hz signal on the –IN input to generate a 0.25LSB error (150 μ V) with the converter running at CLK = 500kHz, its peak value would have to be 16mV. Rearranging the above equation, the maximum sinusoidal signal that can be digitized to a given accuracy is given as:

$$
f_{\leftarrow IN)MAX} = \left(\frac{V_{ERROR(MAX)}}{2\pi V_{PEAK}}\right)\left(\frac{f_{CLK}}{12}\right)
$$

For 0.25LSB error (150µV) the maximum input sinusoid with a 2.5V peak amplitude that can be digitized is 0.4Hz.

Reference Input

The voltage on the reference input of the LTC1287 determines the voltage span of the A/D converter. The reference input has transient capacitive switching currents due to the switched capacitor conversion technique (see Figure 12). During each bit test of the

conversion (every CLK cycle) a capacitive current spike will be generated on the reference pin by the A/D. These current spikes settle quickly and do not cause a problem. If slow settling circuitry is used to drive the reference input, take care to insure that transients caused by these current spikes settle completely during each bit test of the conversion.

Figure 12. Reference Input Equivalent Circuit

HORIZONTAL: 1µs/DIV

Figure 13. Adequate Reference Settling

Figure 14. Poor Reference Settling Can Cause A/D Errors

Figures 13 and 14 show examples of both adequate and poor settling. Using a slower CLK will allow more time for the reference to settle. Even at the maximum CLK rate of 500kHz most references and op amps can be made to settle within the 2µs bit time. For example an LT1790 with a 4.7µF bypass capacitor will settle adequately.

Reduced Reference Operation

The effective resolution of the LTC1287 can be increased by reducing the input span of the converter. The LTC1287 exhibits good linearity over a range of reference voltages (seeTypical Performance Characteristics curves of Change in Linearity vs Reference Voltage). Care must be taken when operating at low values of V_{RFF} because of the reduced LSB step size and the resulting higher accuracy requirement placed on the converter. Offset and Noise are factors that must be considered when operating at low V_{RFF} values.

Offset with Reduced VREF

The offset of the LTC1287 has a larger effect on the output code when the A/D is operated with a reduced reference voltage. The offset (which is typically a fixed voltage) becomes a larger fraction of an LSB as the size of the LSB is reduced. The Typical Performance Characteristics curve of Unadjusted Offset Error vs Reference Voltage shows how offset in LSBs is related to reference voltage for a typical value of V_{OS} . For example a V_{OS} of 0.1mV, which is 0.2LSB with a 2.5V reference becomes 0.4LSB with a 1.25 reference. If this offset is unacceptable, it can be corrected digitally by the receiving system or by offsetting the –IN input to the LTC1287.

Noise with Reduced VRFF

The total input referred noise of the LTC1287 can be reduced to approximately 200µV peak-to-peak using a ground plane, good bypassing, good layout techniques and minimizing noise on the reference inputs. This noise is insignificant with a 2.5V reference input but will become a larger fraction of an LSB as the size of the LSB is reduced. The Typical Performance Characteristics

curve of Noise Error vs Reference Voltage shows the LSB contribution of this 200µV of noise.

For operation with a 2.5V reference, the 200µV noise is only 0.32LSB peak-to-peak. Here the LTC1287 noise will contribute virtually no uncertainty to the output code. For reduced references, the noise may become a significant fraction of an LSB and cause undesirable jitter in the output code. For example, with a 1.25V reference, this 200µV noise is 0.64LSB peak-to-peak. This will reduce the range of input voltages over which a stable output code can be achieved by 0.64LSB. Now averaging readings may be necessary.

This noise data was taken in a very clean test fixture. Any setup induced noise (noise or ripple on V_{CC} , V_{RFF} or V_{IN}) will add to the internal noise. The lower the reference voltage used, the more critical it becomes to have a noise-free setup.

Overvoltage Protection

Applying signals to the LTC1287's analog inputs that exceed the positive supply or that go below ground will degrade the accuracy of the A/D and possibly damage the device. For example this condition would occur if a signal is applied to the analog inputs before power is applied to the LTC1287. Another example is the input source operating from different supplies of larger value than the LTC1287. These conditions should be prevented either with proper supply sequencing or by use of external circuitry to clamp or current limit the input source. There are two ways to protect the inputs. In Figure 15 diode clamps from the inputs to V_{CC} and GND are used. The second method is to put resistors in series with the analog inputs for current limiting. Limit the current to 15mA per channel. The +IN input can accept a resistor value of 1k but the –IN input cannot accept more than 200 Ω when clocked at its maximum clock frequency of 500kHz. If the LTC1287 is clocked at the maximum clock frequency and 200 Ω is not enough to current limit the input source then the clamp diodes are recommended (Figures 16 and 17). The reason for the limit on the resistor value is the MSB bit test is affected by the value of the resistor placed at the –IN

input (see discussion on Analog Inputs and the Typical Performance Characteristics curve of Maximum CLK Frequency vs Source Resistance).

If V_{CC} and V_{REF} are not tied together, then V_{CC} should be turned on first, then V_{REF} . If this sequence cannot be met, connecting a diode from V_{RFF} to V_{CC} is recommended (see Figure 18).

Because a unique input protection structure is used on the digital input pins, the signal levels on these pins can exceed the device V_{CC} without damaging the device.

APPLICATIONS INFORMATION

A "Quick Look" Circuit for the LTC1287

Users can get a quick look at the function and timing of the LTC1287 by using the following simple circuit (Figure 19). V_{REF} is tied to V_{CC} . V_{IN} is applied to the +IN input and the –IN input is tied to the ground plane. \overline{CS} is driven at 1/32 the clock rate by the 74HC393 and D_{OUT} outputs the data. The output data from the D_{OUT} pin can be viewed on an oscilloscope that is set up to trigger on the falling edge of \overline{CS} (Figure 20). Note the LSB data is partially clocked out before \overline{CS} goes high.
