# **General Description**

The 831724 is a high-performance, differential HCSL clock/data multiplexer and fanout buffer. The device is designed for the multiplexing and fanout of high-frequency clock and data signals. The device has two differential, selectable clock/data inputs. The selected input signal is distributed to four low-skew differential HCSL outputs. Each input pair accepts HCSL, LVDS and LVPECL levels. The 831724 is characterized to operate from a 3.3V power supply. Guaranteed input, output-to-output and part-to-part skew characteristics make the 831724 ideal for those clock and data distribution applications demanding well-defined performance and repeatability. The 831724 supports the clock multiplexing and distribution of PCI Express Generation 1, 2, and 3 clock signals.

### **Features**

- **•** 2:1 differential clock/data multiplexer with fanout
- **•** Two selectable, differential inputs
- **•** Each differential input pair can accept the following levels: HCSL, LVDS, LVPECL.
- **•** Four differential HCSL outputs
- **•** Maximum input/output clock frequency: 350MHz
- **•** Maximum input/output data rate: 700Mb/s (NRZ)
- **•** LVCMOS interface levels for all control inputs
- **•** PCI Express Gen 1,2,3 jitter compliant
- **•** Input skew: 165ps (maximum)
- **•** Output skew: 175ps (maximum)
- **•** Part-to-part skew: 450ps (maximum)
- **•** Full 3.3V supply voltage
- **•** Available in lead-free (RoHS 6) package
- **•** -40°C to 85°C ambient operating temperature

#### **Table 4C. Differential DC Characteristics,**  $V_{DD} = 3.3V \pm 0.3V$ ,  $T_A = -40^{\circ}C$  to 85°C

NOTE 1:  $V_{IL}$  should not be less than -0.3V.

NOTE 2: Common mode input voltage is defined as  $V_{\text{IH}}$ .

# **AC Electrical Characteristics**

**Table 5A. PCI Express Jitter Specifications,**  $V_{DD} = 3.3V \pm 0.3V$ ,  $T_A = -40^{\circ}C$  to 85°C

**NOTE:** Electrical parameters are guaranteed over the specified ambient operating temperature range, which is established when the device is mounted in a test socket with maintained transverse airflow greater than 500 lfpm. The device will meet specifications after thermal equilibrium has been reached under these conditions. The phase noise is dependent on the input signal source. The input signal was generated using a Tektronix HFS9000 Stimulus System. For additional information, refer to the *PCI Express Application Note section* in the datasheet. **NOTE 1:** Peak-to-Peak jitter after applying system transfer function for the Common Clock Architecture. Maximum limit for PCI Express Gen 1<br>is 86ps peak-to-peak for a sample size of 10<sup>6</sup> clock periods.

**NOTE 2:** RMS jitter after applying the two evaluation bands to the two transfer functions defined in the Common Clock Architecture and reporting the worst case results for each evaluation band. Maximum limit for PCI Express Generation 2 is 3.1ps RMS for t<sub>REFCLK\_HF\_RMS</sub> (High

Band) and 3.0ps RMS for t<sub>REFCLK\_LF\_RMS</sub> (Low Band).<br>**NOTE 3:** RMS jitter after applying system transfer function for the common clock architecture. This specification is based on the *PCI Express Base Specification Revision 0.7, October 2009* and is subject to change pending the final release version of the specification. **NOTE 4:** This parameter is guaranteed by characterization. Not tested in production.

#### **Table 5B. HCSL AC Characteristics,**  $V_{DD} = 3.3V \pm 0.3V$ ,  $T_A = -40^{\circ}C$  to 85<sup>o</sup>C

NOTE: Electrical parameters are guaranteed over the specified ambient operating temperature range, which is established when the device is mounted in a test socket with maintained transverse airflow greater than 500 lfpm. The device will meet specifications after thermal equilibrium has been reached under these conditions.

NOTE 1: Measured from the differential input crossing point to the differential output crossing point.

NOTE 2: Defined as skew between input paths on the same device, using the same input signal levels, measured at one specific output at the differential cross points.

NOTE 3: This parameter is defined in accordance with JEDEC Standard 65.

NOTE 4: Defined as skew between outputs on different devices operating at the same supply voltage, same temperature, same frequency and with equal load conditions. Using the same type of inputs on each device, the outputs are measured at the differential cross points. NOTE 5: Measurement taken from differential waveform.

NOTE 6: Measurement from -150mV to +150mV on the differential waveform (derived from Q minus nQ). The signal must be monotonic through the measurement region for rise and fall time. The 300mV measurement window is centered on the differential zero crossing. NOTE 7:  $T_{\text{STABLE}}$  is the time the differential clock must maintain a minimum ±150mV differential voltage after rising/falling edges before it is allowed to drop back into the  $V_{RB}$  ±100 differential range. See Parameter Measurement Information Section. NOTE 8: Measurement taken from single-ended waveform.

NOTE 9: Defined as the maximum instantaneous voltage including overshoot. See Parameter Measurement Information Section.

NOTE 10: Defined as the minimum instantaneous voltage including undershoot. See Parameter Measurement Information Section. Notes continued on next page.

NOTE 11: Measured at crossing point where the instantaneous voltage value of the rising edge of Q equals the falling edge of nQ. See Parameter Measurement Information Section

NOTE 12: Refers to the total variation from the lowest crossing point to the highest, regardless of which edge is crossing. Refers to all crossing points for this measurement. See Parameter Measurement Information Section.

NOTE 13: Defined as the total variation of all crossing voltage of rising Q and falling nQ. This is the maximum allowed variance in the V<sub>CROSS</sub> for any particular system. See Parameter Measurement Information Section.

NOTE 14: Input duty cycle must be 50%.

NOTE 15: Defined as skew between outputs at the same supply voltage and with equal load conditions. Measured at the differential cross points.

### **Additive Phase Jitter**

The spectral purity in a band at a specific offset from the fundamental compared to the power of the fundamental is called the *dBc Phase Noise.* This value is normally expressed using a Phase noise plot and is most often the specified plot in many applications. Phase noise is defined as the ratio of the noise power present in a 1Hz band at a specified offset from the fundamental frequency to the power value of the fundamental. This ratio is expressed in decibels

(dBm) or a ratio of the power in the 1Hz band to the power in the fundamental. When the required offset is specified, the phase noise is called a *dBc* value, which simply means dBm at a specified offset from the fundamental. By investigating jitter in the frequency domain, we get a better understanding of its effects on the desired application over the entire time record of the signal. It is mathematically possible to calculate an expected bit error rate given a phase noise plot.

**Offset from Carrier Frequency (Hz)**

As with most timing specifications, phase noise measurements has issues relating to the limitations of the equipment. Often the noise floor of the equipment is higher than the noise floor of the device. This is illustrated above. The device meets the noise floor of what is shown, but can actually be lower.

The phase noise is dependent on the input source and measurement equipment. The source generator is the Rohde & Schwarz SMA 100A. Phase noise is measured using an Agilent E5052A Signal Source Analyzer.

### **PCI Express Application Note**

PCI Express jitter analysis methodology models the system response to reference clock jitter. The block diagram below shows the most frequently used *Common Clock Architecture* in which a copy of the reference clock is provided to both ends of the PCI Express Link.

In the jitter analysis, the transmit (Tx) and receive (Rx) serdes PLLs are modeled as well as the phase interpolator in the receiver. These transfer functions are called H1, H2, and H3 respectively. The overall system transfer function at the receiver is:

 $Ht(s) = H3(s) \times [H1(s) - H2(s)]$ 

The jitter spectrum seen by the receiver is the result of applying this system transfer function to the clock spectrum  $X(s)$  and is:

 $Y(s) = X(s) \times H3(s) \times [H1(s) - H2(s)]$ 

In order to generate time domain jitter numbers, an inverse Fourier Transform is performed on  $X(s)^*H3(s)^*$  [H1(s) - H2(s)].

For **PCI Express Gen 1**, one transfer function is defined and the evaluation is performed over the entire spectrum: DC to Nyquist (e.g for a 100MHz reference clock: 0Hz – 50MHz) and the jitter result is reported in peak-peak.

**PCIe Gen 1 Magnitude of Transfer Function**

For **PCI Express Gen 2**, two transfer functions are defined with 2 evaluation ranges and the final jitter number is reported in rms. The two evaluation ranges for PCI Express Gen 2 are 10kHz – 1.5MHz (Low Band) and 1.5MHz – Nyquist (High Band). The plots show the individual transfer functions as well as the overall transfer function Ht.

**PCIe Gen 2A Magnitude of Transfer Function**

**PCIe Gen 2B Magnitude of Transfer Function**

For **PCI Express Gen 3**, one transfer function is defined and the evaluation is performed over the entire spectrum. The transfer function parameters are different from Gen 1 and the jitter result is reported in RMS.

**PCIe Gen 3 Magnitude of Transfer Function**  For a more thorough overview of PCI Express jitter analysis methodology, please refer to IDT Application Note: *PCI Express Reference Clock Requirements.*

# **Recommendations for Unused Input and Output Pins**

### **Inputs:**

### **LVCMOS Control Pins**

All control pins have internal pullup or pulldown; additional resistance is not required but can be added for additional protection. A 1k $\Omega$  resistor can be used.

#### **CLK/nCLK Inputs**

For applications requiring only one differential input, the unused CLK/nCLK input can be left floating. Though not required, but for additional protection, a 1k $\Omega$  resistor can be tied from CLK to ground.

### **Outputs:**

### **Differential OutputS**

The unused differential outputs can be left floating. We recommend that there is no trace attached. Both sides of the differential output pair should either be left floating or terminated.

# **Wiring the Differential Input to Accept Single-Ended Levels**

*Figure 1* shows how a differential input can be wired to accept single ended levels. The reference voltage  $V_1= V_{DD}/2$  is generated by the bias resistors R1 and R2. The bypass capacitor (C1) is used to help filter noise on the DC bias. This bias circuit should be located as close to the input pin as possible. The ratio of R1 and R2 might need to be adjusted to position the  $V_1$ in the center of the input voltage swing. For example, if the input clock swing is 2.5V and  $V_{DD} = 3.3V$ , R1 and R2 value should be adjusted to set  $V_1$  at 1.25V. The values below are for when both the single ended swing and  $V_{DD}$  are at the same voltage. This configuration requires that the sum of the output impedance of the driver (Ro) and the series resistance (Rs) equals the transmission line impedance. In addition, matched termination at the input will attenuate the signal in half. This can be done in one of two ways. First, R3 and R4 in parallel should equal the transmission

line impedance. For most  $50\Omega$  applications, R3 and R4 can be 100 $\Omega$ . The values of the resistors can be increased to reduce the loading for slower and weaker LVCMOS driver. When using single-ended signaling, the noise rejection benefits of differential signaling are reduced. Even though the differential input can handle full rail LVCMOS signaling, it is recommended that the amplitude be reduced. The datasheet specifies a lower differential amplitude, however this only applies to differential signals. For single-ended applications, the swing can be larger, however  $V_{II}$  cannot be less than -0.3V and  $V_{H}$  cannot be more than  $V_{DD}$  + 0.3V. Though some of the recommended components might not be used, the pads should be placed in the layout. They can be utilized for debugging purposes. The datasheet specifications are characterized and guaranteed by using a differential signal.

**Figure 1. Recommended Schematic for Wiring a Differential Input to Accept Single-ended Levels**

### **Differential Clock Input Interface**

The CLK /nCLK accepts LVDS, LVPECL, HCSL, and other differential signals. Both differential inputs must meet the  $V_{PP}$  and  $V_{CMR}$  input requirements. *Figures 2A to 2D* show interface examples for the CLK/nCLK input driven by the most common driver types. The input interfaces suggested here are examples only. Please consult with the

**Figure 2A. CLK/nCLK Input Driven by a 3.3V LVPECL Driver**

**Figure 2C. CLK/nCLK Input Driven by a 3.3V LVDS Driver**

vendor of the driver component to confirm the driver termination requirements. For example, in Figure 2A, the input termination applies for IDT LVPECL drivers. If you are using an LVPECL driver from another vendor, use their termination recommendation.

**Figure 2B. CLK/nCLK Input Driven by a 3.3V LVPECL Driver**

**Figure 2D. CLK/nCLK Input Driven by a 3.3V HCSL Driver**

### **VFQFN EPAD Thermal Release Path**

In order to maximize both the removal of heat from the package and the electrical performance, a land pattern must be incorporated on the Printed Circuit Board (PCB) within the footprint of the package corresponding to the exposed metal pad or exposed heat slug on the package, as shown in *Figure 3.* The solderable area on the PCB, as defined by the solder mask, should be at least the same size/shape as the exposed pad/slug area on the package to maximize the thermal/electrical performance. Sufficient clearance should be designed on the PCB between the outer edges of the land pattern and the inner edges of pad pattern for the leads to avoid any shorts.

While the land pattern on the PCB provides a means of heat transfer and electrical grounding from the package to the board through a solder joint, thermal vias are necessary to effectively conduct from the surface of the PCB to the ground plane(s). The land pattern must be connected to ground through these vias. The vias act as "heat pipes". The number of vias (i.e. "heat pipes") are application specific and dependent upon the package power dissipation as well as

electrical conductivity requirements. Thus, thermal and electrical analysis and/or testing are recommended to determine the minimum number needed. Maximum thermal and electrical performance is achieved when an array of vias is incorporated in the land pattern. It is recommended to use as many vias connected to ground as possible. It is also recommended that the via diameter should be 12 to 13mils (0.30 to 0.33mm) with 1oz copper via barrel plating. This is desirable to avoid any solder wicking inside the via during the soldering process which may result in voids in solder between the exposed pad/slug and the thermal land. Precautions should be taken to eliminate any solder voids between the exposed heat slug and the land pattern. Note: These recommendations are to be used as a guideline only. For further information, please refer to the Application Note on the Surface Mount Assembly of Amkor's Thermally/Electrically Enhance Leadframe Base Package, Amkor Technology.

**Figure 3. P.C. Assembly for Exposed Pad Thermal Release Path – Side View (drawing not to scale)**

### **Recommended Termination**

*Figure 4A* is the recommended source termination for applications where the driver and receiver will be on a separate PCBs. This termination is the standard for PCI Express™ and HCSL output

types. All traces should be  $50\Omega$  impedance single-ended or  $100\Omega$ differential.

**Figure 4A. Recommended Source Termination (where the driver and receiver will be on separate PCBs)**

*Figure 4B* is the recommended termination for applications where a point-to-point connection can be used. A point-to-point connection contains both the driver and the receiver on the same PCB. With a matched termination at the receiver, transmission-line reflections will be minimized. In addition, a series resistor (Rs) at the driver offers flexibility and can help dampen unwanted reflections. The optional resistor can range from 0Ω to 33Ω. All traces should be  $50\Omega$ impedance single-ended or 100Ω differential.

**Figure 4B. Recommended Termination (where a point-to-point connection can be used)**

## **Power Considerations**

This section provides information on power dissipation and junction temperature for the 831724. Equations and example calculations are also provided.

#### **1. Power Dissipation.**

The total power dissipation for the 831724 is the sum of the core power plus the power dissipated at the output(s). The following is the power dissipation for  $V_{DD} = 3.3V \pm 0.3V = 3.6V$ , which gives worst case results.

NOTE: Please refer to Section 3 for details on calculating power dissipated at the output(s).

Total Power<sub>MAX</sub> =  $V_{DD}$ <sub>MAX</sub>  $*$  ( $I_{DD}$ <sub>MAX</sub>) = 3.6V  $*$  128mA = 460.8mW

#### **2. Junction Temperature.**

Junction temperature, Tj, is the temperature at the junction of the bond wire and bond pad, and directly affects the reliability of the device. The maximum recommended junction temperature is 125°C. Limiting the internal transistor junction temperature, Tj, to 125°C ensures that the bond wire and bond pad temperature remains below 125°C.

The equation for Tj is as follows: Tj =  $\theta_{JA}$  \* Pd\_total + T<sub>A</sub>

Tj = Junction Temperature

 $\theta_{JA}$  = Junction-to-Ambient Thermal Resistance

Pd\_total = Total Device Power Dissipation (example calculation is in section 1 above)

 $T_A$  = Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance  $\theta_{l}$  must be used. Assuming no air flow and a multi-layer board, the appropriate value is 37.0°C/W per Table 6 below.

Therefore, Tj for an ambient temperature of 85°C with all outputs switching is:

85°C + 0.4608W \*37.0°C/W = 102.05°C. This is below the limit of 125°C.

This calculation is only an example. Tj will obviously vary depending on the number of loaded outputs, supply voltage, air flow and the type of board (multi-layer).

#### Table 6. Thermal Resistance  $\theta_{JA}$  for 32 Lead VFQFN, Forced Convection

#### **3. Calculations and Equations.**

The purpose of this section is to calculate power dissipation on the IC per HCSL output pair.

HCSL output driver circuit and termination are shown in *Figure 5.*

**Figure 5. HCSL Driver Circuit and Termination**

HCSL is a current steering output which sources a maximum of 17mA of current per output. To calculate worst case on-chip power dissipation, use the following equations which assume a  $50\Omega$  load to ground.

The highest power dissipation occurs at  $V_{DD-MAX}$ .

- Power =  $(V_{DD\_MAX} V_{OUT})$  \*  $I_{OUT}$ , since  $V_{\text{OUT}} = I_{\text{OUT}} * R_{\text{L}}$
- Power =  $(V_{DD}$   $_{MAX} I_{OUT} * R_L) * I_{OUT}$
- Power =  $(3.6V 17mA * 50 $\Omega$ ) * 17mA$

Total Power Dissipation per output pair = **46.8mW**
