

DESCRIPTION

The MC34064 is an undervoltage sensing circuit designed specifically for use as a reset controller in microprocessor-based systems. It offers the designer an economical, space-efficient solution for low supply voltage detection when used in combination with a single pullup resistor. Adding one capacitor offers the functionality of a programmable delay time after power returns. The MC34064 consists of a temperature stable reference comparator with hysteresis, high-current clamping diode and open collector output stage capable of sinking up to 60mA. The MC34064's RESET output is specified to be fully functional at $V_{IN}=1V$. A major improvement over competing products is the glitch-free supply current during undervoltage detection. Competing products demand a step function increase in operating current during the time that you least want or need it: during power loss. See Product Highlight below.

IC ELECTRICAL CHARACTERISTICS

Unless otherwise specified, the following specifications apply over the operating ambient temperature $0^{\circ}\text{C} \leq T_A \leq 70^{\circ}\text{C}$ for the MC34064 and $-40^{\circ}\text{C} \leq T_A \leq 85^{\circ}\text{C}$ for the MC33064. Low duty cycle pulse testing techniques are used which maintains junction and case temperatures equal to the ambient temperature.

TYPICAL APPLICATION CIRCUITS

Figure 15 – Low Voltage Microprocessor Reset

A time delayed reset can be accomplished with the addition of C_{DLY} . For systems with extremely fast power supply rise times (<500ns) it is recommended that the RC_{DLY} time constant be greater than $5.0\mu s$. $V_{TH(MPU)}$ is the microprocessor reset input threshold.

Figure 18 – MOSFET Low Voltage gate Drive Protection

Overheating of the logic level power MOSFET due to insufficient gate voltage can be prevented with the above circuit. When the input signal is below the 4.6 volt threshold of the MC34064, its output grounds the gate of the L^2 MOSFET.

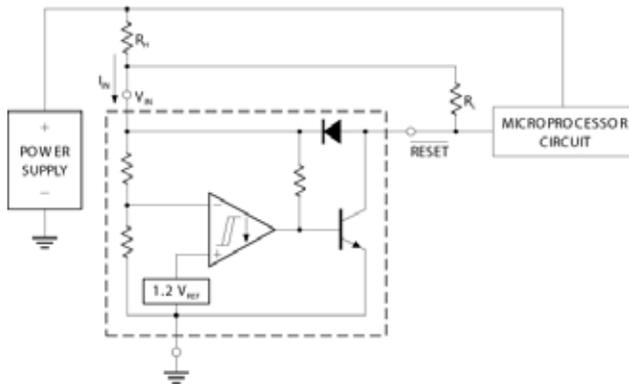

TYPICAL APPLICATION CIRCUITS

$$V_H = \frac{4.6R_H}{R_L} + 0.02$$

$$V_{TH(LOWER)} = 340R_H \cdot 10^{-6}$$

Where: $R_H = 150\Omega$
 $R_L = 1.5\Omega = 10k\Omega$

Comparator hysteresis can be increased with the addition of resistor R_H . The hysteresis equation has been simplified and does not account for the change of input current I_{IN} as V_{CC} crosses the comparator threshold. An increase of the lower threshold. $\Delta V_{TH(LOWER)}$ will be observed due to I_{IN} which is typically $340\mu A$ at $4.59V$. The equations are accurate to $\pm 10\%$ with R_H less than 150Ω and R_L between $1.5k\Omega$ and $10k\Omega$.
